No fumes; flat on top for propagating plants, and other purposes, and burns 24 hours without attention. Price 21s; easy payments, 3s. per month. Send 2d. for photo, etc. HOLLIDAY and CO., Albert Place, Congleton.

TO-DAY! AND FOR YEARS AND YEARS PAST the XL ALL Specialities are and have been the best on the market. Where is the Gardener who does not pin his faith to one or the other of these celebrated Insecticides or Fertilisers? XL ALL FERTILISER has pleased all who have used it this season. The Sales of XL ALL FUMIGATOR prove that it is more popular than ever. XL ALL LIQUID NICOTINE INSECTICIDE is always spoken of by gardeners and growers as the most deadly to Mealy Bug, Thrip, etc. XL ALL WINTER WASH for dormant Trees acts like magic, clearing the Trees and Bushes of all Insects' Eggs, Moss, and Fungoid Growths. XL ALL LAWN SAND, a weed eradicator and fertiliser for weedy and poor lawns. XL ALL WEED KILLER used once a year "No weeds can live." Please ask your Nurseryman, Seedsman, or Florist for a copy of my small pink list, giving particulars of these and many other XL ALL Preparations, which can be obtained from the Horticultural Trade throughout the World. G. H. RICHARDS, Manufacturer and Patentee, 234 Borough High Street, London, S.E.

THE GARDENERS' MAGAZINE.

NOTES OF THE WEEK.

Past and Present.

In alluding to the horticultural aspects of the year on which we have just entered, it appears desirable to briefly refer to a few of the more important events of the past twelve months, with a view to advantage being taken of the lessons they are so well able to afford. There is no occasion for us to give a history of the year in its relation to the gardening art, for all the exhibitions and functions of importance have been fully reported in these pages at the time of their occurence, and the new introductions that have obtained recognition from the leading societies have been described, and a considerable proportion illustrated. Our object in referring to them is to make such deductions from the past as are likely to be useful for future guidance. The exhibition side of horticulture received a full share of attention during the year, and the shows held by the principal societies, both in London and the provinces, were for the most part eminently successful. The exhibitions held by the Royal Horticultural Society at the Temple and Holland Park were highly successful from every point of view, and the interest, the usefulness, and the attractions of the fortnightly displays have been fully maintained and appreciated. On the other hand, the autumn fruit show was so poorly attended that the function will not have a place in the society's programme for the current year. We regret this, because the cultivation of hardy fruits requires the fullest encouragement, and it is possible that the interest might have been maintained had the commercial side of fruit growing been given greater prominence, and the display thereby rendered more diversified and attractive. The society has accomplished much useful work in other directions, and especially at Wisley, and it is satisfactory to have such evidence as the continuous increase of Fellows affords that its efforts in the furtherance of horticulture are fully appreciated by all who are more or less interested in horticulture. The success of the National Rose Society may well be described as phenomenal, for in the increase of membership, in its exhibitions, and in its activity in other directions all previous records were broken; and there is full justification for the belief that these in their turn will be surpassed this year. This success is unquestionably due to the well devised policy adopted some years ago, and continued until the present time, of giving such encouragement to all classes of roses as would ensure their adequate representation at the exhibitions, and of giving the members something, other than tickets of admission to the shows, in return for their subscriptions. The National Sweet Pea Society also achieved a full measure of success during the year; it held two successful exhibitions, conducted a trial of varieties of much value to cultivators, and materially increased the number of its members. This increase in numerical strength and in usefulness may safely be attributed to the successful carrying out of a policy at once comprehensive and vigorous. The Perpetual-Flowering Carnation Society, the most recent of the special societies, appears to have had a fairly successful year, for it held two exhibitions, both of a high order; that in December was extremely beautiful and had much value from an educational standpoint. With reference to the National Dahlia Society, it must be said that at the present time it is in a state of transition, and has the promise of attaining to a higher degree of popularity and usefulness than for some years past. As our readers have been informed, the London Dahlia Union has been amalgamated with it, and this combination, uniting as it does all classes of dahlia growers, should add greatly to the numerical strength of the society, and to its capacity for useful work. As the result of the amalgamation, a more advanced policy has been adopted, and strenuous efforts will, we understand, be made to extend its usefulness in directions other than holding exhibitions. The society will hold two exhibitions, and at both classes for cactus dahlias specially adapted for garden decoration, will, we believe, be provided, and for the first time the pæony-flowered varieties will receive encouragement. An endeavour is being made to arrange for a comprehensive trial of cactus dahlias, and if this can be carried out the society will have an opportunity of showing that it recognises its responsibilities, and intends to render service of far-reaching importance to the general body of cultivators. Horticultural exhibitions of a minor character were held as usual in large numbers, and in many instances they were of so high an order of merit as to prove to demonstration that the societies are doing excellent work. In many cases the exhibitions were decidedly poor, and especially was this so where societies have been so greatly multiplied that every village has its flower show. There are some whose opinions are deserving of respect who say that it is difficult to have too many exhibitions, but it should be remembered that

SIR DANIEL MORRIS, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S.

when the societies in any particular district are so numerous as to be in excess of requirements there is a great waste of money and energy, and an insufficiency of funds to stimulate a really satisfactory competition. There are large numbers of districts where three or four societies could with advantage be amalgamated, and the exhibitions of the combined society be held at the several places in their turn. By this arrangement there would be a saving in the ordinary expenses, and a much larger sum be available for prizes. The result of this change would be exhibitions more interesting and attractive, and certainly more useful in their influence upon the advancement of horticulture. We trust this suggestion will receive careful consideration when arrangements are being made for active work during the year. It will not be found an easy task to combine several societies in a certain district, but considering how important are strong societies, an endeavour should be made to bring about a concentration of effort where it is seen to be specially desirable. Referring more directly to the horticultural programme of the year we need only say that it will be a full one, and that the preparations now being made by the leading societies indicate a degree of activity that speaks well for the advancement of horticulture. So far as this journal is concerned, there certainly will be no relaxation of effort to keep readers fully informed on the most advanced practice in the cultivation of ornamental and useful plants, and of the merits of new introductions as they make their appearance. The illustrated accounts of the more important gardening districts have been so highly appreciated that we shall continue this interesting feature throughout the year. We shall also give direct attention to roses, sweet peas, orchids, dahlias, chrysanthemums, fruits, vegetables, ornamental trees and shrubs, and hardy plants generally.

Sir Daniel Morris, K.C.M.G., etc., whose portrait we now present to our readers, has laboured hard for the empire for many years, and in many places, and though there must be some regret that his unique ability will now be no longer at the service of the nation as heretofore, no one will grudge him the well-earned rest to which he has now retired. After an education at Cheltenham, Royal College of Science, South Kensington, and Dublin University, where he was Gold Medallist, Sir Daniel Morris was appointed Assistant Director of the Ceylon Botanic Gardens in 1877, and while there he successfully investigated the coffee-leaf disease. In 1879 he was appointed Director of the Royal Botanic Gardens, Jamaica. He explored British Honduras in 1882, and reported upon the resources of St. Helena in 1883. It was in 1886 that he became Assistant Director of the Royal Gardens, Kew, and in the following year he became treasurer of the Royal Horticultural Society, a post he occupied until 1890, and in which he did a very great deal to put the society on a sound basis, and so pave the way for the great success that has followed. Sir Daniel went on a special mission to the West Indies in 1890-91, and in 1895 he visited the Bahamas, in each case with a view to improving the agricultural industry. His appointment as scientific adviser to the West India Royal Commission in 1896-7 was everywhere regarded as well chosen, and it was no wonder to any who were acquainted with his ability and wide knowledge, when, in 1898 he was appointed Imperial Commissioner of the West Indian Agricultural Department. In this capacity Sir Daniel Morris has been eminently successful in reviving the fallen industries of the West Indies. Under his guidance the cotton industry and the sugar industry have been re-established, while the banana trade has greatly increased, and cocoa, coffee, arrowroot, citrus fruits, etc., have all been taken up with a will. High cultivation, selection, and improvement of varieties, and prevention of waste have been insisted upon by Sir Daniel and by those capable assistants he gathered around him when he first took charge. He had also a great belief in the value of conferences and the bringing together of growers, traders, and scientists, and that belief led him to organise no fewer than seven inter-colonial agricultural conferences, the last of which, as our readers will remember, was at Jamaica, and was rudely interrupted by the great earthquake. He received his knighthood in 1903 as an acknowledgment of services rendered, but the steady revival of prosperity in the West Indies is the crowning glory of Sir Daniel's work. Sir Daniel Morris is the author of numerous reports upon Colonial matters, and treatises on special Colonial subjects, such as rubber, sisal, hemp, cacao, etc., so that what with studying, travelling, organising, and writing, his life has been an extremely busy, and we may add, an extremely useful one also.

"Gardeners' Magazine" Almanack.—With this issue we present our readers with a double-page almanack for the current year. This has been prepared with special reference to its usefulness in the garden office, and trade establishment, and contains the dates of all the principal exhibitions and meetings that had been arranged at the time of going to press. The fine gold medal hybrid tea rose, William Shean, with which the almanack is illustrated, is one of the many fine varieties raised by Messrs. Alex. Dickson and Sons, of Newtownards.

Christmas Flowers at Belvoir Castle.—Mr. W. H. Divers informs us that sixty-seven species and varieties of hardy plants were in bloom in the Belvoir Castle Gardens on Christmas Day. These were: Achillea aurea; Antirrhinum majus; Anemone fulgens, A. blanda, purple, and A. blanda, pink; Alyssum saxatile, fl. pl.; Arabis alpina, A. alpina, fl. pl., A. bellidifolia; Arbutus andrachne; Berberis Darwini, B. japonica; Ceanothus Gloire de Versailles; Clematis Jackmani, C. Fair Rosamond; Chimonanthus fragrans; Chrysanthemum indicum, many varieties; Coronilla emerus; Crocus Imperati; Cytisus albus; Daisy, common and double in variety; Daphne mezereum; Doronicum excelsum; Erica carnea, E. stricta, E. vagans; Erodium Manescavi; Erysimum Peroffskianum, E. compactum; Escallonia Ingrami; Gentiana acaulis; Helleborus Caucasicus, H. niger; Ionopsidium acaule; Iberis sempervirens; Jasminum nudiflorum; Laurestinus; Leptospermum scoparium, the Manuka tree of New Zealand, which has grown outside here since 1896; Myosotis dissitiflora Dyeræ; Lupinus polyphyllus, pink; Phlox amœna, P. Newry Seedling; Pyrus Japonicum; Polyanthus; Primrose, common yellow and Wilson's Blue; Pyrethrum parthenifolium; Rhododendron Nobleanum; Rose Banksian, and many other varieties; Rosemarinus officinalis; Saxifraga ligulata; Scilla siberica; Strawberry Vicomtesse H. de Thury; Spiræa fillipendula, fl. pl.; Statice sinuata; Stocks, several varieties; Tritelia uniflora; Tussilago fragrans; Ulex europæus or Gorse; Veronica Blue Gem; Vinca major; Viola Bullion; Violets, single Russian and Lady Hume Campbell double; Wallflower, Salmon Queen, Whitethorn, or May (Cratægus oxyacantha). The severe weather experienced since Mr. Divers' note was written has made an end of flowers in the open, and given Britishers an opportunity of participating in the "pleasures" of the so-called "old-fashioned" winter.

Lack of Holly Berries.—One very noticeable feature of the markets during the Christmas season was the great lack of berries on the holly exposed for sale. In the autumn one could not walk through woods and gardens without noticing how finely the holly was berried in the majority of cases; but after the dry weather there came a spell of wet weather, followed by bright days and warm nights that sent the sap surging through the stems and branches, and the berries, like all too many of our apples in the orchard, were literally pushed off the trees; at least, this is the only explanation one can give for the loss of holly berries. Mistletoe, especially imported produce, has been and still is, remarkably fine, being unusually well berried.

Snow and Frost.—As we write practically the whole of England, Wales, and Scotland is white with snow, and in the cities and towns the work of clearing snow from the streets and paths is giving work to the otherwise unemployed. It is Wednesday morning, and the sun is shining and making everything look beautiful under its winter mantle. On Sunday snow began to fall, and continued more or less until Monday night, when very severe weather set in, and Tuesday, December 29, was one of the most wintry days experienced for a very long time, hard frost, keen, driving wind, and heavy snow combining to make travelling a matter of great difficulty everywhere and by any means. We learn of trains snowed up for many hours together, and of cities like Aberdeen practically isolated for a quite long time. Altogether from six inches to a foot of snow fell, but in some districts, as at Alton in Hampshire, and in the extreme northern counties of England, the snow fell to a depth of 2ft. and more. The frost prevented the snow from melting, and even in London there were ten degrees of frost. At Dover and in Paris 14 degrees were registered on Monday night and early Tuesday morning. It is probable that such a severe storm and fall of snow has not been experienced since that dreadful day, January 18, 1881, when an east wind piled up the snow, stopped traffic, and caused a large number of deaths. In March, 1891, there was a heavier fall of snow than on either of these other occasions, but wind and frost were in no sense severe. During the present week the snow has spoiled the prospects of good skating, and the sharp frost has reduced the pleasure of snowballing, but where there are good slopes tobogganing has been, and still is, in full swing.

Tunbridge Wells Gardens.—The second of the two illustrated articles on the gardens round Tunbridge Wells will appear in our next issue.

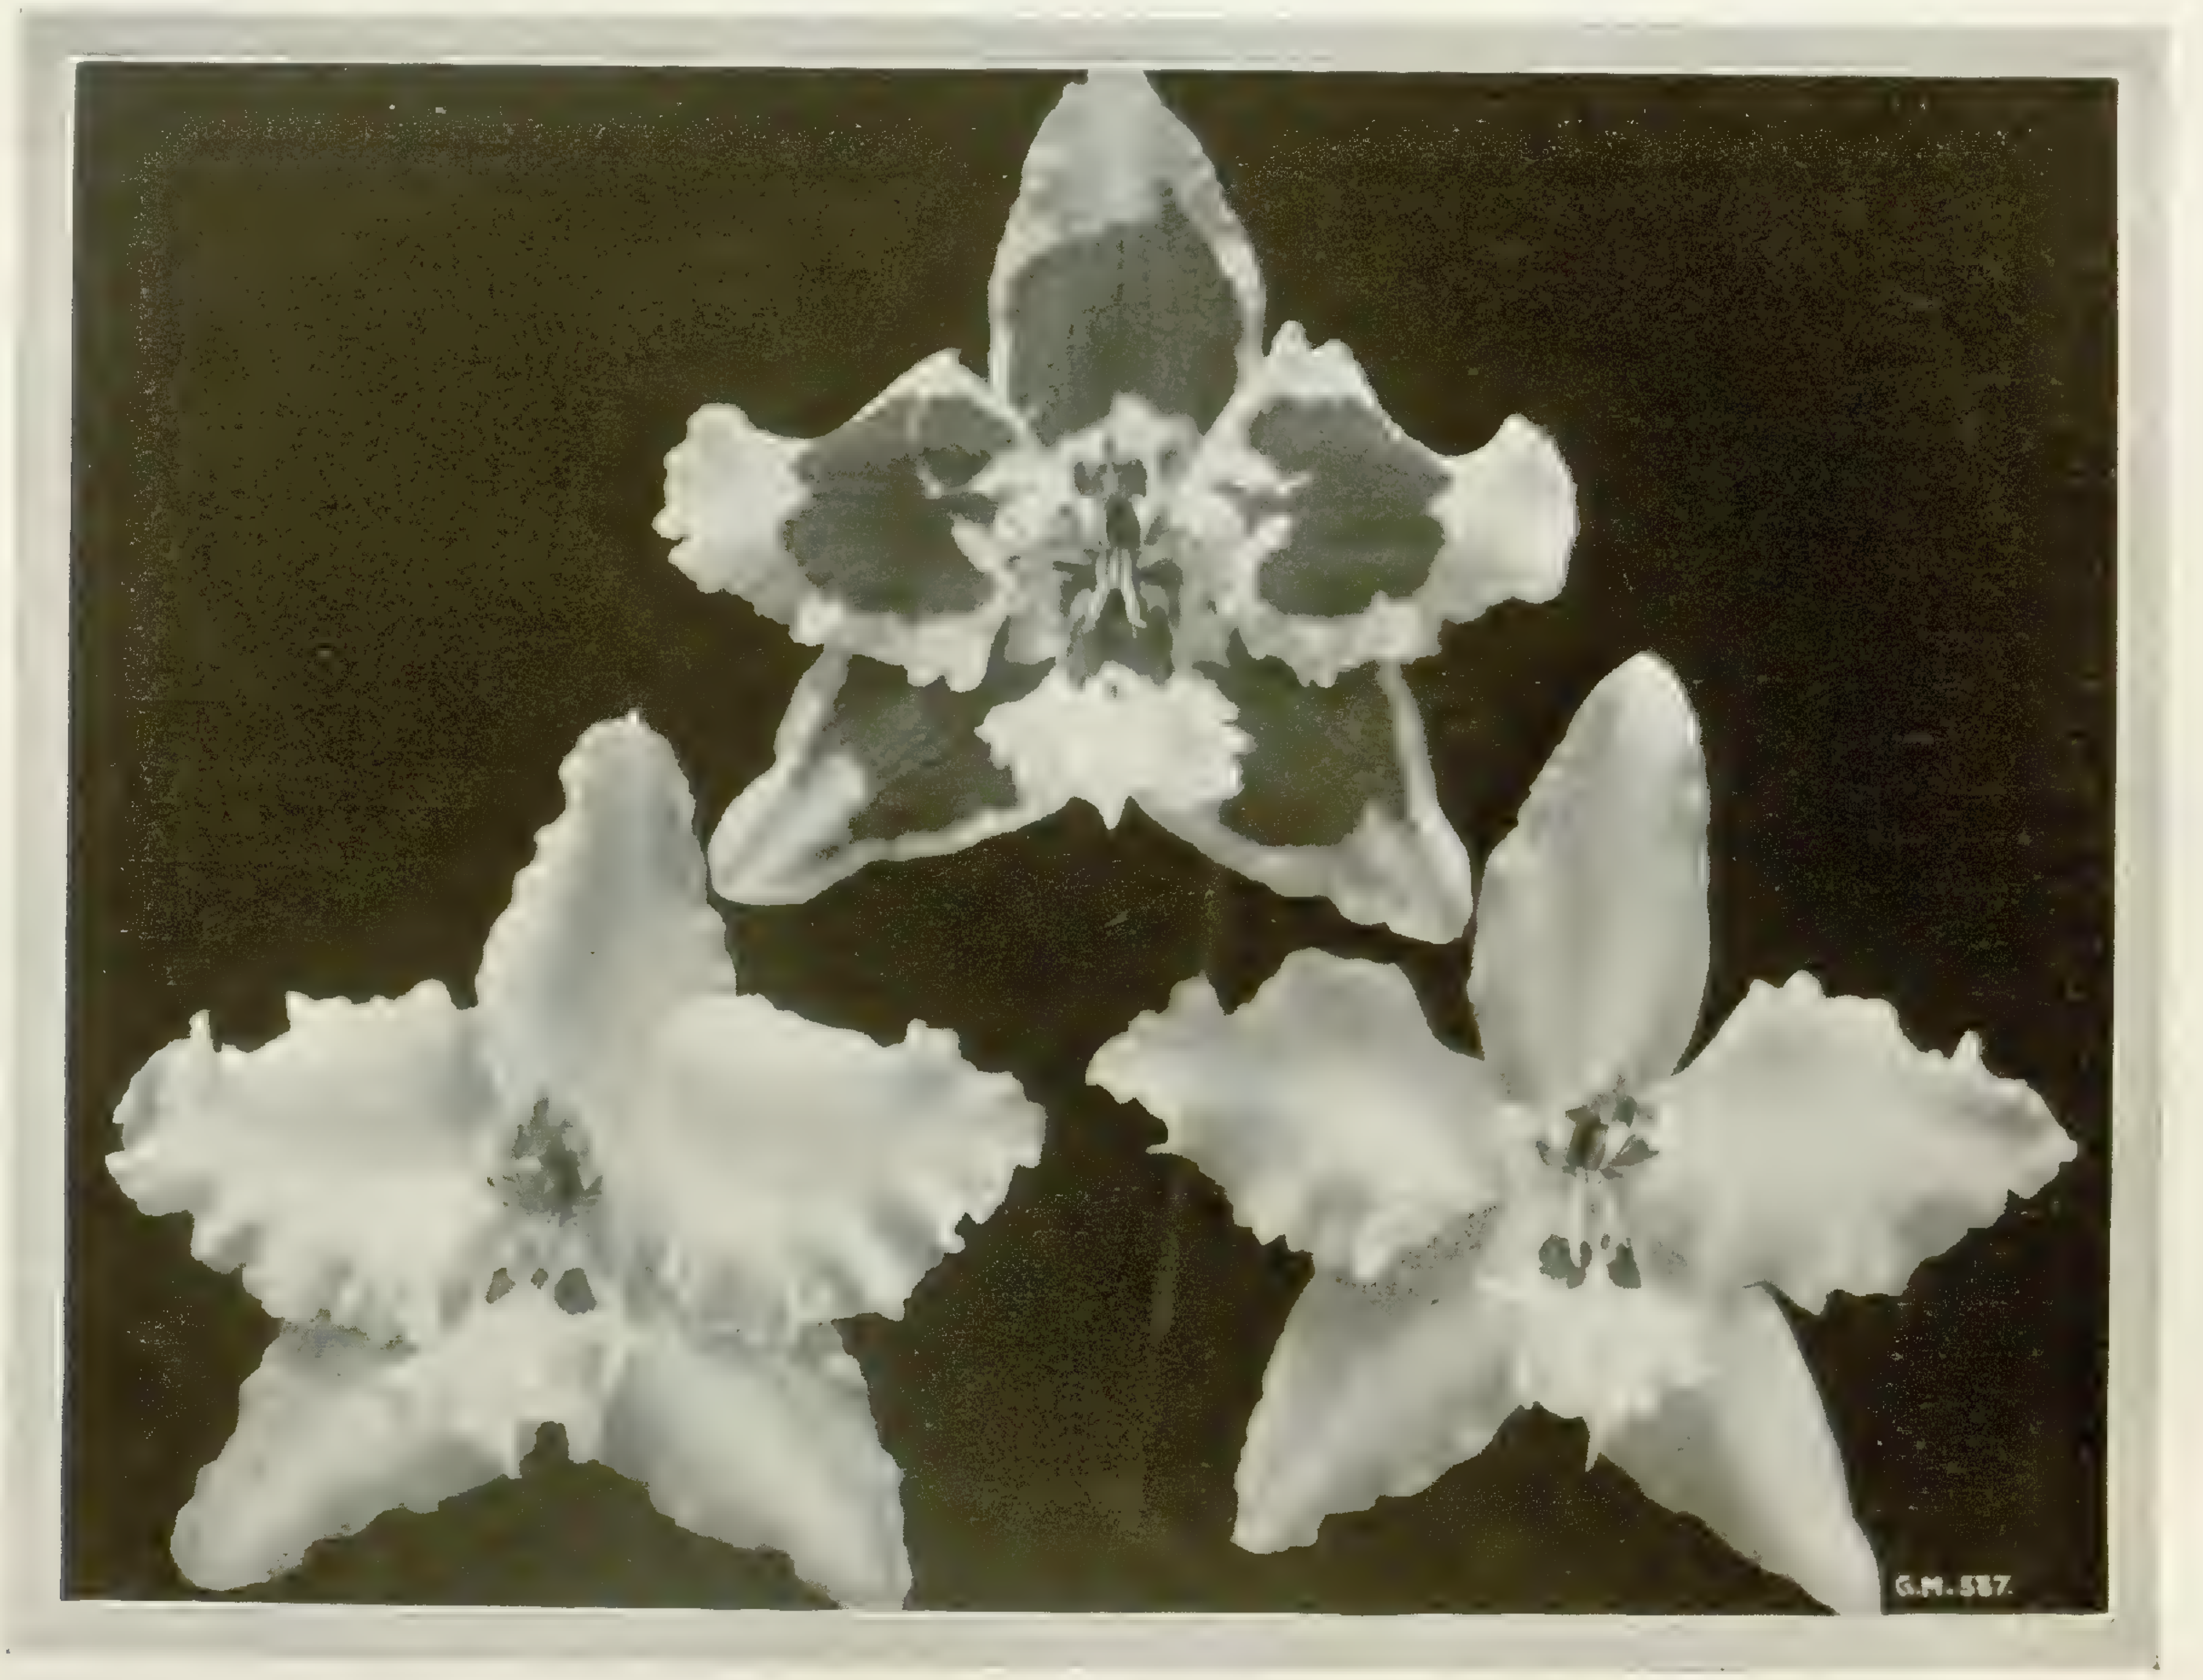
Garden Cities.—The next meeting of the London branch of the British Gardeners' Association will be held on Saturday, January 9, 1909, in the Charles Dickens' Room at Carr's Restaurant, Strand, at 7.30 p.m., when Mr. Cyril Harding, of the Parks Department, Cardiff, will deliver an address upon "Garden Cities: What they are, and what they might be." Professional gardeners are invited to attend whether B.G.A. members or not.

Lecture on Cypripediums.—Mr. Budgett, of Tramore, Henbury, Bristol, whose garden was described in our issue of December 19, gave a most useful and interesting lecture on "Cypripediums" before the Bristol Gardeners' Association a few days ago. Mr. Budgett is a keen amateur grower, and a vice-president of the society, and he obtained a gold medal for his fine exhibit of cypripediums at the recent Bristol Chrysanthemum Show. The lecturer kept chiefly to the insigne section, and he gave a demonstration of the method of cross-fertilisation, showing also how insects effect pollination in the Lady's Slipper Orchids. Mr. Budgett's fund of humour was as much appreciated as his details of cultivation.

Prizes at R.H.S. Meetings in 1909.—The Royal Horticultural Society has decided not to hold a great fruit show during the autumn of 1909, but they have arranged for a series of competitive classes at the various fortnightly meetings at Westminster. Prizes will be offered to both amateur and trade growers. On January 12 there will be four classes for grapes; on January 26 six classes for forced vegetables and salads; February 9, three classes for dessert pears; and February 23, three classes for late dessert pears. Other classes, for later dates have not yet been made known, but we may add that substantial cash prizes for bulbs will be offered on March 9, the Dutch Bulb Growers' Society and Mr. R. Sydenham both contributing considerable sums. On April 20 Messrs. Barr and Sons' silver cup for daffodils will be competed for, and the Veitch Memorial Medal and £5 will be offered for the best group of winter-flowering carnations exhibited on April 6. The Sherwood Cup will be of the value of 20 guineas, intead of ten guineas as previously, and it will be offered for the best group of orchids (traders' or amateurs') staged at the Temple Show.

A SEEDLING ORCHID.

The creation of plants is so vastly interesting to those who are engaged in the work, that the life history of a single individual among the thousands of orchids that are daily and momentarily depending on one for care and attention cannot be overlooked. It may be that the seed has been sown only a few days, and a careful examination bestowed by the aid of a magnifying glass reveals the fact that one individual seed has become plump and so far advanced that its transparent green marks it distinctly from the seeds surrounding it, which display little, if any, signs of activity.



SEEDLING ODONTOGLOSSUMS.
Raised from the same pod of seeds.

Naturally such a tiny atom of life becomes a special care, and with its development interest grows into attachment, as we notice its original vigour is maintained throughout its various stages of development. As if in response to the special care and encouragement it receives, this particular "pet" may develop its growth to such an unusual extent that there is every reason for believing it may create a record as regards the period between seed sowing and the plant reaching its flowering size.

The fascination that has been so great before now becomes excitement when a tiny spike appears and the flower buds advance to that stage where they give some indication of what the flower may be. If it should be an Odontoglossum crispum seedling, derived from the intercrossing of two of the renowned blotched varieties, some evidence is given at an early stage of bud development as to whether or not the blotched characteristics of the parents will be inherited by the offspring, and if such indications are present, the interest becomes greater as the buds reach maturity and the flowers expand. If expectations are realised, then we smile at the writers who contend that the blotched and spotted varieties are hybrids, or, if not, at the most only sports, and, therefore, possessing recessive characters, can only produce the typical forms

We have now achieved success, but how often do we experience disappointment? The fates have been more kind to some of us than to others, and we are satisfied with a reasonable share of the successes.

A most remarkable and, to me, a most significant thing has happened in my own experience, and I know there are others who can support this view, and it is that we invariably find the first plant to flower among a batch of seedlings to be the best variety. So even for those who have grown grey in experience with seedling orchids, there is something very stimulating in the prospect of flowering a first seedling from a new cross

The accompanying illustration will convey some of the pleasures and disappointments attaching to raising seedling orchids. The upper flower represents Odontoglossum ardentissimum Peetersii, and the white forms beneath were obtained from the same seed pod. O. crispum Chapmaniæ, readers may remember, produced flowers from the first pseudo-bulb about two years from seed sowing.

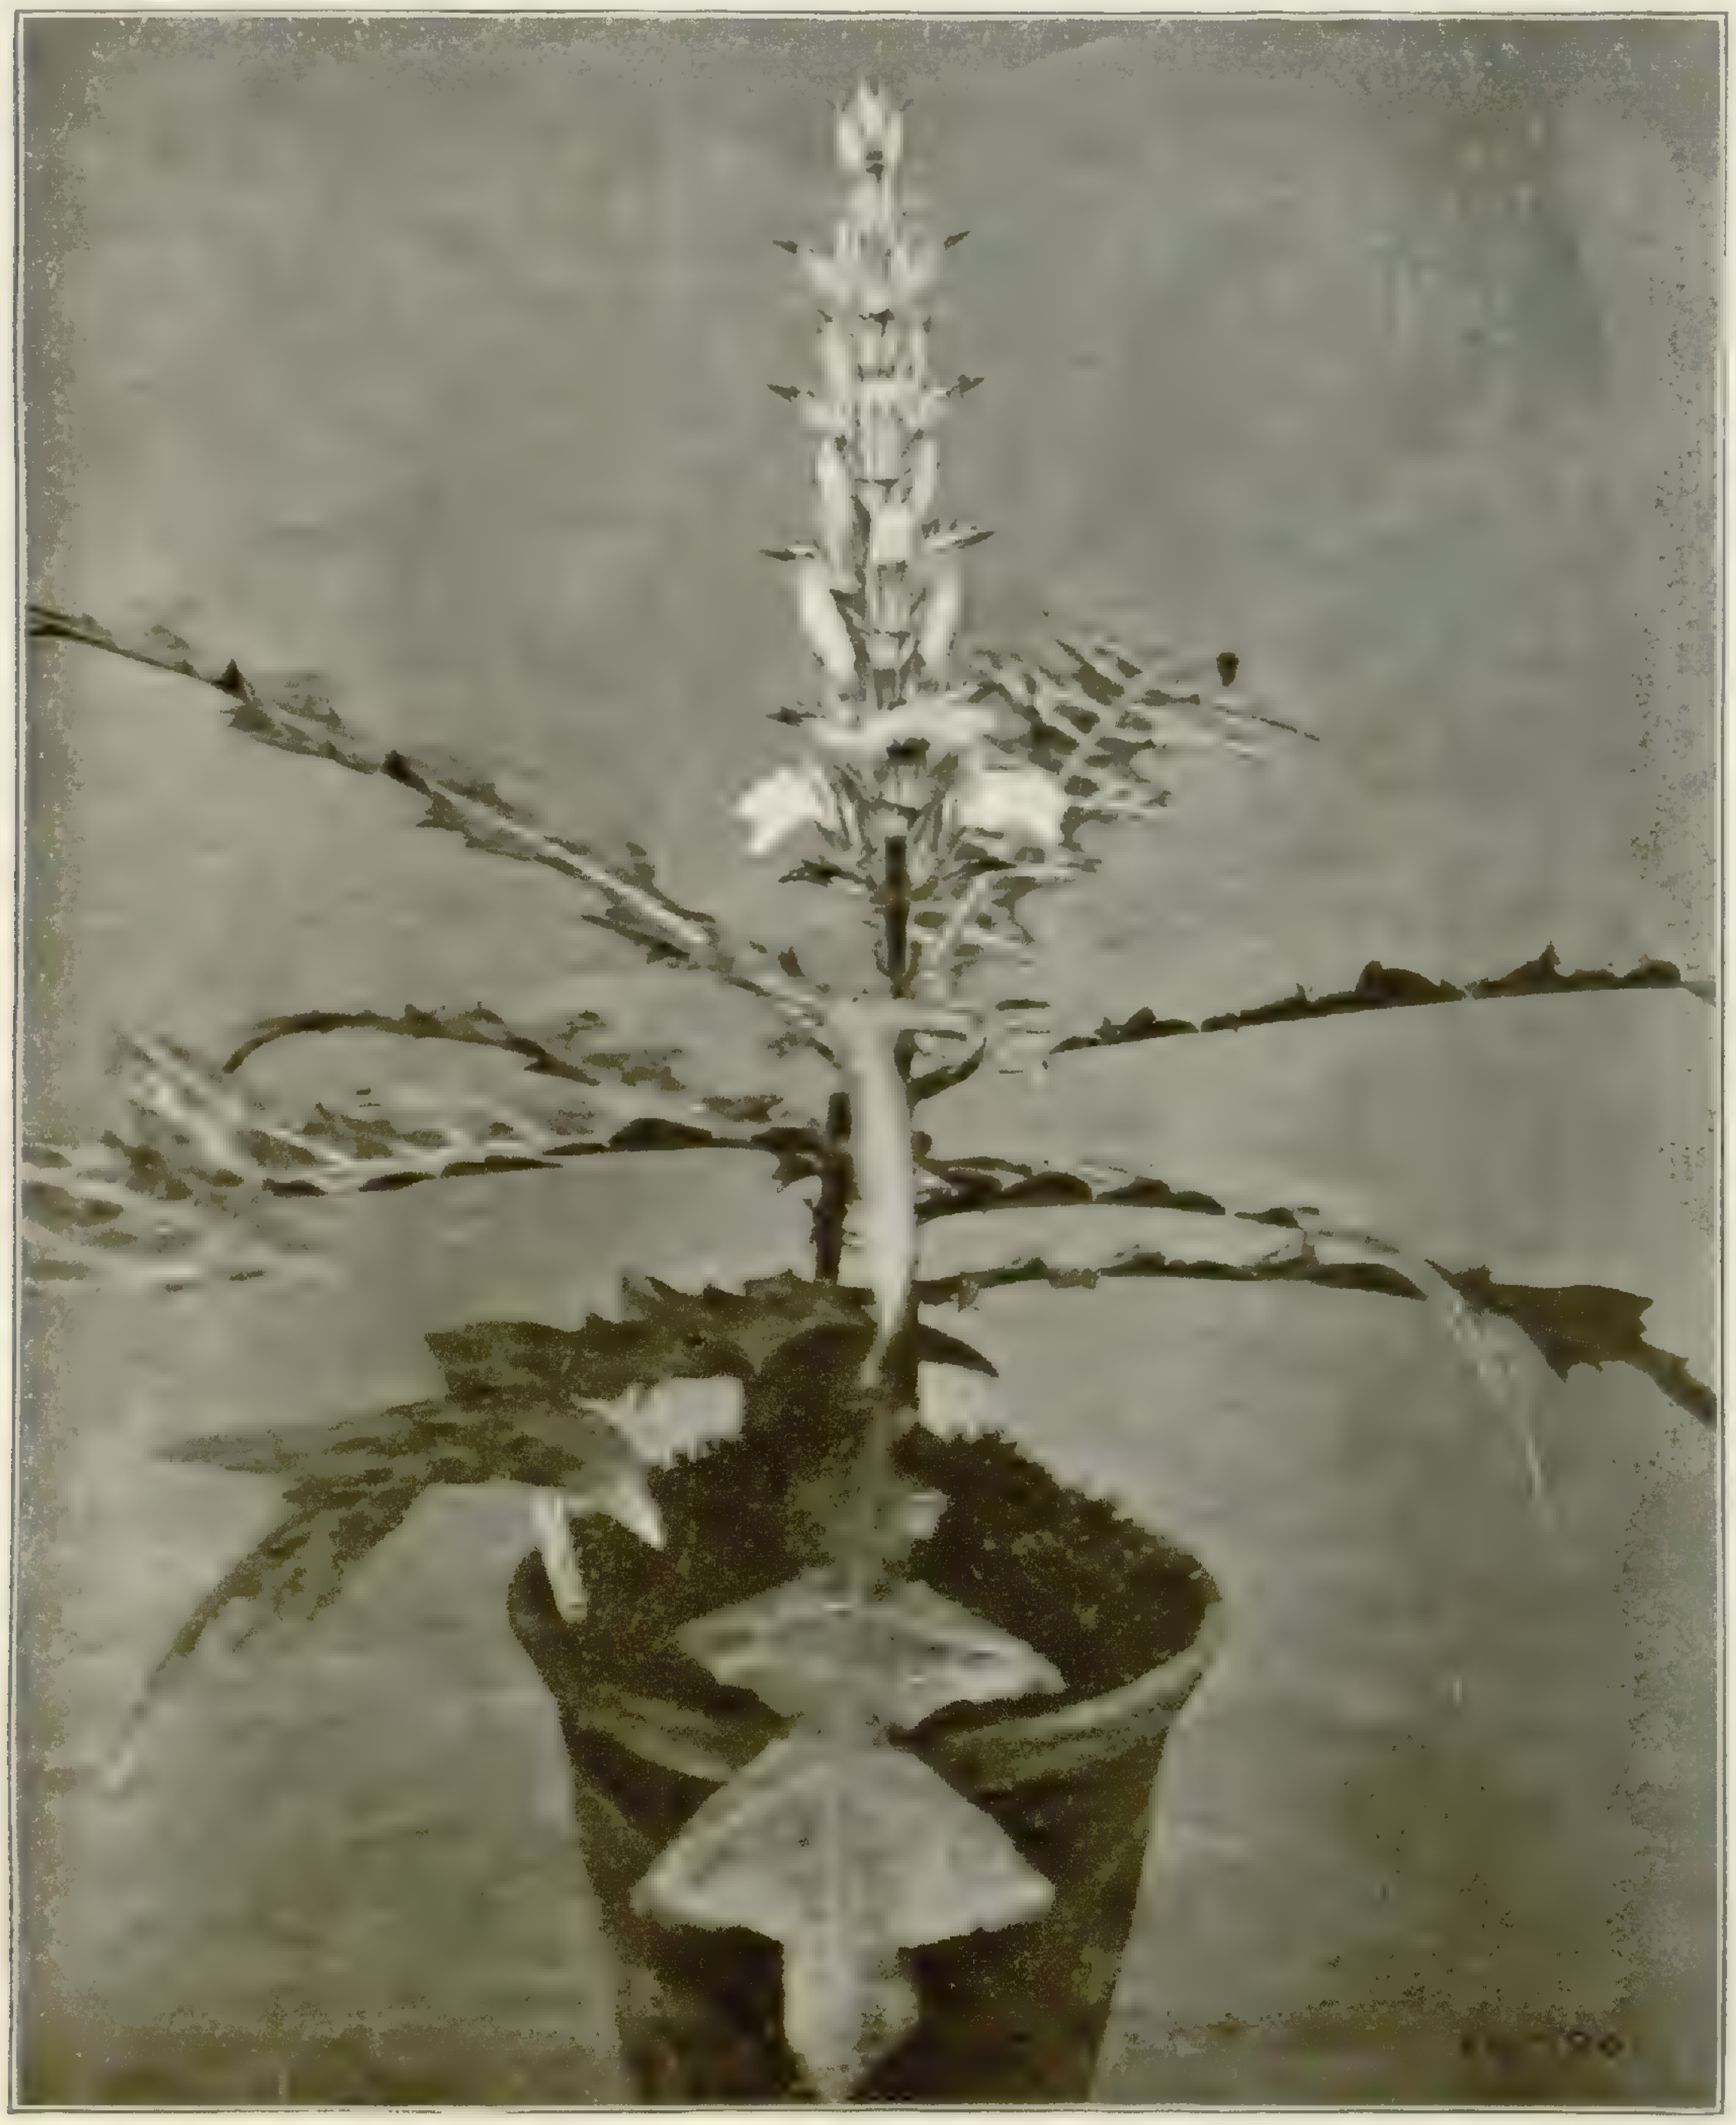
Oakwood Gardens.

COLOUR.

In the autumn, when we see the manifold tints of green which have hitherto prevailed in the landscape rapidly assuming nearly all the tints of the rainbow, even including brilliant hues of crimson and scarlet, which represent exactly the complementary colour of the greens they displace, the question of what colour really is becomes of peculiar interest.

The answer is really that colour is no corporeal thing at all, but only an effect. We may take substances which have most potent dyeing qualities which they can impart to anything with which they can be associated, but, though this seems to contradict our statement, we shall see that it really does not do so. The appearance which we term colour really results from a capacity in the substance concerned to absorb certain constituents of the rays of light and throw off the rest, this rest affecting our eyes in such a way as to agree with our ideas of a certain colour, which we then apply to the substance. In point of fact, however, we view the substance not by virtue of what is in it, but of what it has rejected or failed to appropriate. As red is the complementary colour of green, that is, a set of light rays of separate character, we are entitled to assume that all through the growing season, when foliage is green, it is really appropriating the red rays of light; and in this connection, it is a singular fact, that cultural experiments under red glass have demonstrated that red light greatly stimulates growth, while on the other hand, when green tinted glass was tried at Kew, the results were far from satisfactory. This process of absorption and rejection of the light rays must be an extremely subtle one. Let us, however, first explain their nature more fully.



ACANTHUS MONTANUS.

A handsome species, exhibited by Messrs. J. Veitch and Sons, at R.H.S. meeting on December 22, 1908, when it received a F.C.C. Leaves large, deeply cut, and marbled in two shades of green; flowers, white.

The light which we receive from the sun strikes us as white, which we consider as really colourless, but the sunbeam is an extremely complex affair. It is made up of an infinite series of light and heat waves, which vary greatly in length. Mixed up together they produce no colour effect at all; but when passed through a prism, a triangular bar of cut glass, it is found that the several lengths of the waves determine differences of direction in passing through the differing thicknesses of the glass; and, as a consequence, they are sorted out and distributed in a regular row, forming a colour beam of light which is termed a "spectrum." A sun-lit rain shower does precisely the same thing when we see a rainbow; the white light is broken up into its constituent colours, and always in regular order. In the artificial spectrum, it is found that beyond the visible or colour-producing waves there are others, invisible, which are heat waves, with which, however, we have nothing to do in this connection, though they are doubtless very potent factors in vegetative activity.

Now, in leaves, which change colour markedly in the autumn, and in many flowers which pass through a series of different tints in the course of development and decay, it must be a very subtle process of alteration which induces at one time the absorption of light waves of a certain length, i.e., tint, and their rejection at another, when a different set is selected instead. Then, too, we have multi-coloured flowers of many kinds in which different parts of the petals possess different capacities in this respect in curiously arranged spots and stripes, or in other varied ways. Then, too, the colours, as shown by the "spectrum" or rainbow, are pure colours, there is no mixture of tints at all. Though they grade delicately into one another, and so form intermediate hues, this is quite a different thing from the infinite gamuts of other tints which exist in nature, and in man's artificial productions. Thus in many colours we have a power of absorption and rejection which does not merely mean breaking up the sunbeam and adopting and rejecting adjacent sections of its component colours, but of doing so with all sorts of selected mixtures of non-adjacent ones, just as a painter might dip his brush into the numerous varied tints on his palette as he has to do when he attempts to reproduce them on his canvas.

Finally, we may well give a thought to the wondrous sensibility of our eyes which can not only receive this marvellous complex of rejected and reflected light rays on the retina, but has a nervous system delicate enough to carry the full impression to our brain, and thus enable us to enjoy the infinity and beauty of colour around us.

CHAS T. DRUERY, V.M.H., F.L.S.

CYMBIDIUM EBURNEO-LOWIANUM.

This distinct and handsome orchid was the first cymbidium hybrid introduced. It was raised by Messrs. J. Veitch and Sons, Chelsea, first flowering in 1889, when it received a first-class certificate from the Royal Horticultural Society on March 12 of that year. The annexed figure represents a noble specimen of this hybrid in the collection at Westonbirt. This plant ten years ago was growing in a six-inch pot, it now occupies a teak tub twenty inches in diameter, the plant having been gradually shifted on as it became root-bound. At the last Ghent show this specimen formed the centrepiece of Colonel Holford's exhibit, carrying 24 spikes and 124 flowers. This hybrid shows the usual combination of characters of the two parent species, the leaves being long and gracefully arching in which they much resemble the seed parent. The racemes are quite intermediate, bearing from three to eight flowers each, and ten spikes come well up out of the foliage, these being freely produced annually from healthy established plants. Like the majority of cymbidium hybrids it is a free grower, which makes it a very popular orchid. Here at Westonbirt, all cymbidiums are growing together in a house with a cool intermediate atmospheric temperature.

Westonbirt. H. G. ALEXANDER.

Lady Gardeners not wanted in Austria.—The question of the establishment of schools and classes for women gardeners came up for discussion at the recent meeting of the Imperial Austrian Horticultural Society, and it was discussed with a good deal of warmth. The scheme was rejected by a very large majority, and the president, who was known to favour the proposals, was not re-elected.

DEW AND FROST.

In the vegetable kingdom, the heat of the sun is the cause of growth, and its light the cause of maturity. Animals may live with little or no light, but no green-leaved plant can come to perfection without it. The sun's rays are both those of heat and light. Were it not for the wise prevention of the accumulation upon the earth of the heat received from the sun, all life upon our globe would be destroyed.

Evaporation and the radiation of heat into space from the earth during the night, when it receives little in return, accomplish this purpose, and these means are the source of great benefit. When the surface of the earth has, by this radiation of heat, become colder than the surrounding air, the moisture of the air is condensed upon it in the form of dew, just as when moisture appears on the outside of a glass of ice-water upon being brought from the cold outside air into a warm room. The value of dew to vegetation is manifested in long periods of severe drought. This moisture gathers where it is most needed, on low plants, the roots of which do not penetrate the earth deeply, and on foliage near the ground.

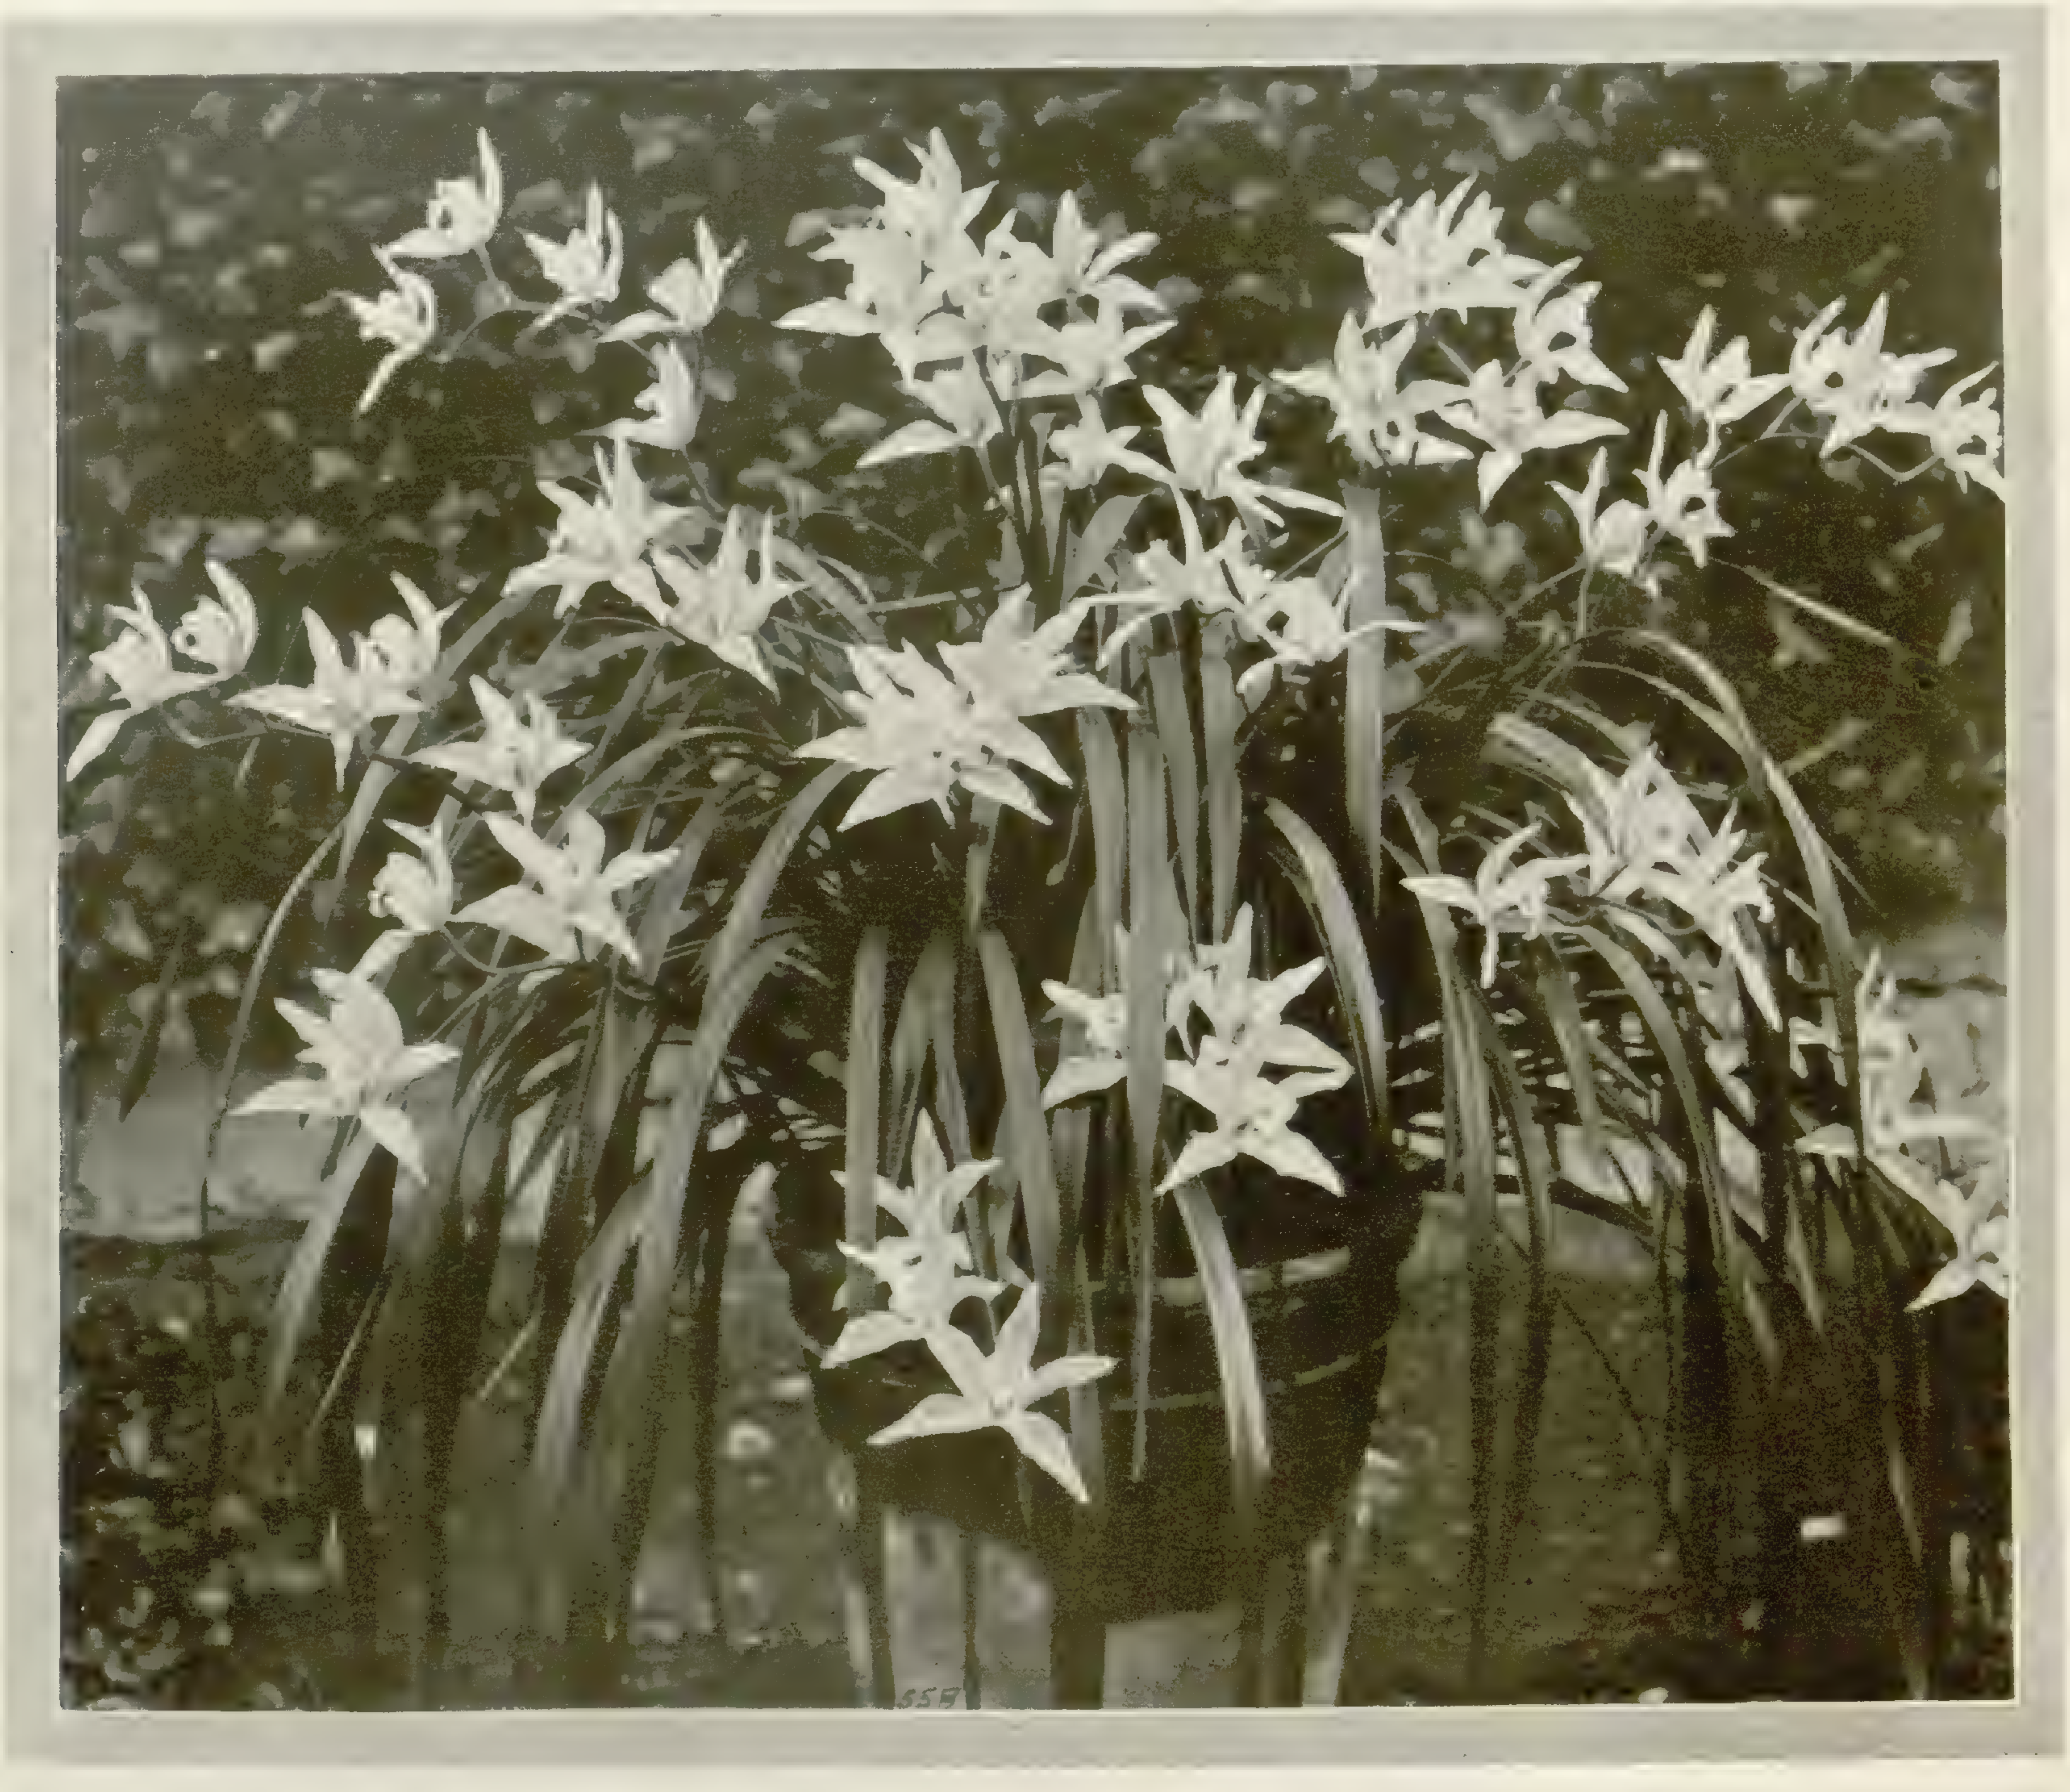
Investigations at Rothamsted, Herts, showed that dew is much richer in plant food than rain, containing twice as much nitrogen, which may serve in some degree to explain its remarkably invigorating effect on vegetation. The precipitation of moisture upon tender vegetation must diminish the cold which occasioned it, and thus prevents the injury that might arise from that cause. The partial prevention of cold on an object near the ground by the interposition of a screen between it and the sky, is due to the reflection of heat by the lower surface of the screen back to the object. This compensates in part for the loss by radiation. The gardener avails himself of this in protecting his plants in cold and clear nights by the interposition of screens, which are most effective when not in contact with the vegetation to be protected. Clouds similarly prevent injury from cold at night by radiating heat to the earth in return for what they intercept from the earth. The lower the clouds the more effective they are. Fog or clouds of smoke have the same effect as clouds of vapour.

The reason why depressed locations suffer most from cold and frost by radiation is that they are more becalmed; and there must also be less dew in them, because of the calm atmosphere which provides the moisture. It is true that at considerable altitudes the air becomes colder as the height increases, but on hills, in cold and clear nights, the frosts are less severe in consequence of the movement in the atmosphere. The dew, which has been deposited upon vegetation by condensation from the atmosphere will become hoar or white frost when the object upon which it has settled is cooled by sufficient radiation to congeal the water into crystals of ice; frost is impossible unless the thermometer falls as low as 44 deg. F.

Plants supplied with heat and moisture may grow for a short time in darkness; but there will be no development of chlorophyll or leaf-green, and they cannot thrive. Plants, in all stages of growth, need the presence of atmospheric air, from the seed requiring oxygen for its germination to the plant which acquires its chief supply of carbon from the air. Water is absolutely necessary in the economy of vegetation.

The management of plants under glass, whether they are to be transferred to the open ground or not, requires an acquaintance with the effects of these various agents and phenomena, so that they may be made to harmonise in the production of a sturdy and healthy vegetation. If a relative excess of either is permitted, failure is certain. A spindling growth will result from too much light or heat; too luxuriant growth from an excess of moisture and heat; and the plants are apt to damp off from much moisture and deficient light.

Harpenden. J. J. Willis.



A FINELY-FLOWERED SPECIMEN OF CYMBIDIUM EBURNEO-LOWIANUM.
In the collection of Lieut.-Colonel Holford, Westonbirt.

Hippeastrums are in many cases throwing up strong spikes, and unless recently potted they should now have some assistance from liquid manure or some approved fertiliser, as the development of the large flowers must severely tax the bulbs. Those which have been stored under stages will require to be examined weekly, as it frequently happens that the spikes are damaged in the early stages of growth by neglect from overcrowding or damping.—Thomas Smith, Walmsgate Gardens, Louth.

GREENHOUSE ANNUALS.

At the present time the tendency is to grow under glass large quantities of a few given subjects rather than to secure as much variety as is reasonably possible in the space to be filled, and this tendency has driven many things almost out of cultivation, and especially such things as are unsuited for house decoration. I am no advocate for the general mixing up of subjects, yet one cannot but regret losses of really beautiful plants, and no class of plants has suffered more from this cult of the big batches than the annuals, and it is quite refreshing now and then to meet with a well-grown group or plant of some old favourite of this class.

For the purpose of these notes I interpret the word annual as meaning any plant which may be raised from seed, and will flower and die within any period of twelve months, no matter when these months begin or end, as I fail to see why plants which go through their course of existence between January 1 and the end of December have any more claim (except that of a foolish custom) to be called annuals, than those which go through the same process, say, from July to the following June.

The plants of this class which I name below, appear to me to be sufficiently beautiful to need very little impetus when fashions change to make them again popular, but almost all of them appear to have suffered in loss of popularity during recent years. Of course, one knows that there are still to be seen occasionally well-grown batches of herbaceous calceolarias, balsams, and, perhaps, still more often of celosias—apart from the cockscomb type, a type that always struck me as more monstrous than beautiful. Another annual which has increased rather than fallen off in popularity in recent years—this popularity being due to its value for house decoration—is the Mock Cypress, Kochia scoparia tricophylla, a very elegant plant at all stages, but more especially in its autumn dress.

The newer forms of nicotiana, such as N. Sanderæ, the flowers of which are carmine-coloured and fairly fixed, and the N. Sanderiana in a variety of colours are at present enjoying a certain amount of popularity, and there is also no question that the newer forms of schizanthus sent out as S. hybrida are particularly and deservedly popular at the present time, few plants giving such a display of elegant flowers in many delicate colours from such a small amount of pot room. Ipomæa rubro cærulea might be much more often seen than it is, for thinly trained over a roof it takes up but little room; and in fact, in addition to its beauty, it may be made a useful adjunct in affording a little shade to plants below. For the same purpose, or for baskets, the various thunbergias, such as T. alata and T. aurantiaca are excellent, and may be used with charming effect.

A not too well-known annual is Exacum affine, which is one of the neatest and most shapely plants for growing in small pots, and a batch of it provides a wealth of greyish blue flowers effective for massing or for facing up groups of other plants with which it may associate in colour. Alonzoa Warscewiczi, with its rosy scarlet flowers, is a very telling and free-flowering annual, covering quite a long season when well grown. Datura cornucopia is a handsome, but little seen plant, good for decorating large conservatories in summer when these are often semi-bare. The browallias and torenias might also be more often grown, and in fact, the plants mentioned are only a small number of annuals, or of plants best treated as annuals, that are sure to some day again become popular.

Shipley Hall Gardens.

GOLDEN-LEAVED TREES.

The judicious use in parks or gardens of trees whose leaves are of other colours than green is of considerable advantage from an artistic standpoint, for such trees make distinct breaks of colour, and if planted tastefully blend beautifully with the prevailing hue, and serve to brighten up the landscape at a period when the flowers of most trees have fallen. A comparatively wide selection of trees is at hand for the purpose, and their leaves may be golden, purple, bronze, silver, or variegated. It is, however, with the former only that we are dealing at the present moment, and a considerable number of such trees to select from are at hand.

Golden-leaved trees comprise both deciduous and evergreen subjects, and examples may be obtained for almost any position. They may be used in a diversity of ways, each having its peculiar merit. The larger-growing kinds may be placed in conspicuous positions in large or small groups, whilst as isolated specimens they are equally advantageous. Such groups formed on hillsides are frequently effective, for, in an elevated position, they can be seen from a considerable distance, especially when backed up by green-foliaged trees. Isolated examples are also commendable, especially for lawns and other conspicuous places. The smaller-growing kinds may be requisitioned for the neater parts of the garden, where they are equally at home mixed with purple, silver, or bronze-foliaged subjects, or planted to form simple golden masses, whilst some may be used successfully as dot plants in shrubberies, especially where the prevailing hue is of a somewhat sombre character.

The group may be roughly divided into two divisions, evergreen and deciduous. The former is composed largely of conifers, the only other family which produces suitable material being the holly. Coniferous trees may be divided again into two groups, golden and golden variegated. In the former group the leaves are golden throughout, assuming a more or less greenish tinge towards winter, whilst in the latter the leaves may be striated with green or gold, as in many yews, or the gold and green may be in patches. The latter condition is very noticeable in some of the cupressuses, and varieties exhibiting this character should be avoided, for they rarely behave satisfactorily. The golden patches frequently die, and the variegation gives the trees a more or less diseased appearance. In the following notes varieties of this description are not mentioned.

Cupressus Lawsoniana provides several golden varieties, which assume the same habit as the type, and grow to a considerable size. They are increased by means of cuttings in autumn, or by grafting on to stocks of the type in spring. Good varieties are aurea, lutea, and gracilis aurea. The latter is of very elegant habit, and a distinct acquisition. The Japanese C. obtusa provides several varieties, good forms being aurea, tetragona aurea, and Crippsi. The latter is a strong-growing, richly-coloured variety of good habit, whilst tetragona aurea is of slow growth, rather low stature, and good colour.

In the Retinospora group (C. pisifera) the best golden variety is plumosa aurea. This forms a distinctly beautiful specimen of plumose habit, with delicate golden leaves. It is well adapted for a conspicuous place on a lawn. The American Arbor-vitæ (Thuya occidentalis) provides several golden varieties; aurea and lutea are the best, but they are inferior in merit to the various varieties of cupressus. Thuya plicata aurea is a strong-growing form of the "canoe cedar," whilst zebrina, a variety of the same species, has foliage curiously barred with green and gold. A golden variety of the Chinese Arbor-vitæ (Thuya orientalis) is in cultivation. This is of rather dense, compact habit, and of slow growth. In addition to these there are golden varieties of Pinus sylvestris, Pinus cembra, and the common spruce. The various yews are very ornamental, but more frequently assume a bush-like habit than tree-like proportions. Good ones are T. baccata elegantissima, Barroni, Dovastoni aurea variegata, adpressa aurea, and fastigiata aurea.

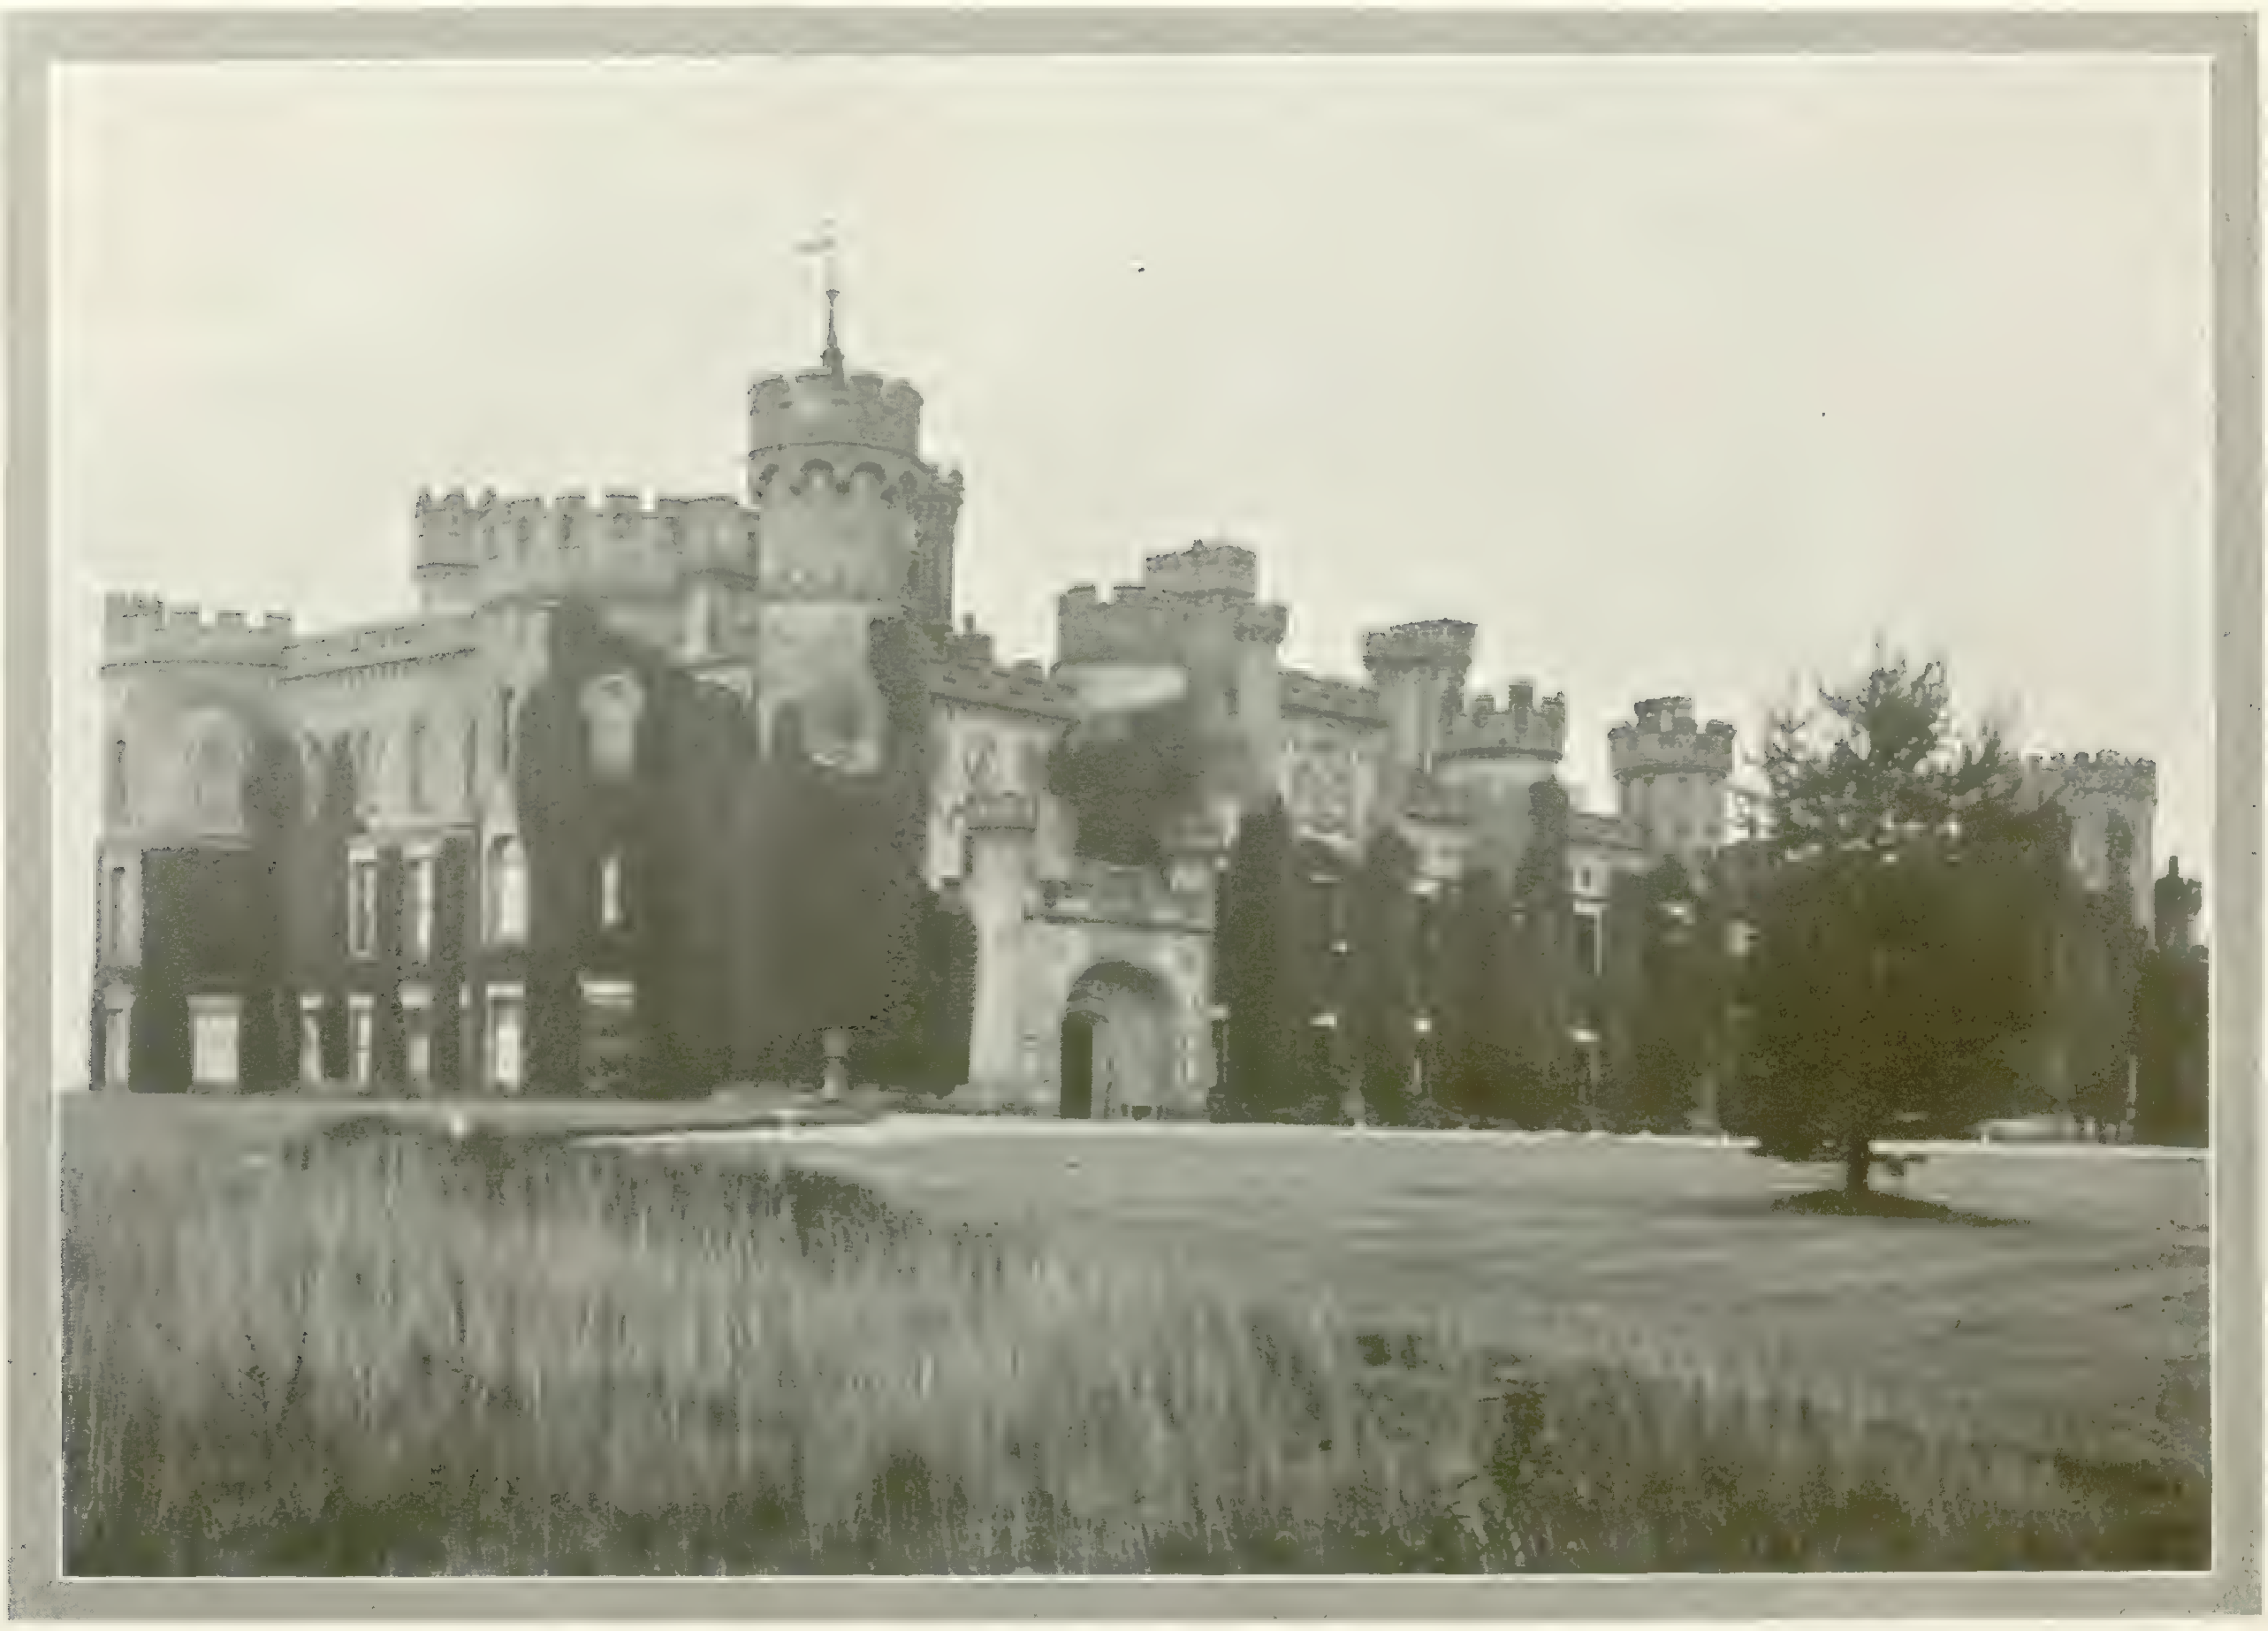
The golden hollies are exceedingly valuable subjects. Some of the best are Golden Queen, Golden Milkmaid, Watereriana, aurea, marginata, latifolia, and Lawsoniana.

For general purposes the deciduous section of the group is possibly of greater value than the evergreen set, for the various varieties thrive in places where coniferous trees would not have much chance. Catalpa bignonioides aurea is one of the best-coloured trees we possess, the colour being a rich gold, whilst it remains good from the time the leaves appear until they fall. Unfortunately, it is of low stature, growing in width more rapidly than in height. Amongst the sycamores and maples there are several golden-leaved and golden-variegated varieties. A few of the most conspicuous are Acer negundo californicum aureum, also known as A. odessanum, a conspicuous and strong-growing tree of good colour; A. negundo aureo-variegatum, a variegated form of the same type: A. Prinz Handjery, a golden-leaved form of the sycamore, of rich colour when the leaves expand, but fading to a yellowish-green tinge towards midsummer: a golden-variegated form of the sycamore, known as flavo-marginatis, is conspicuous, and keeps its colour throughout the summer and autumn, while lutescens, a golden-leaved Acer platanoides, is very pretty.

A set of three elms provide change, one of them, a form of Ulmus campestris, known as Louis van Houtte, being specially worthy of notice. It is of strong growth, and rapidly forms a fine specimen. A form of the same species, known as antarctica aurea, is recognised by its weak growth and small golden leaves, whilst U. montana fastigiata aurea is a golden form of the fastigiate mountain elm. Two oaks are of value, Quercus pedunculata Concordia and Q. rubra aurea, both having rich golden foliage. For damp ground Alnus glutinosa aurea and Populus deltoidea aurea are both useful trees, the latter being a particularly fast grower, and a good subject to plant for a quick effect. Amongst ashes, a golden-variegated form of Fraxinus americana, called aucubæfolia, is showy, and worth a place. In addition to the above-mentioned, there are several of inferior merit, a few of which are Ptelea trifoliata aurea, Pyrus malus aurea, Laburnum vulgare foliis aureis, Acer dasycarpum lutescens, and Pyrus aria chrysophylla. As a miniature tree the golden form of the Japanese maple, Acer japonicum, is very beautiful, while the golden-leaved varieties of Acer palmatum are equally desirable.

W. DALLIMORE.

Kew.



ERIDGE CASTLE, TUNBRIDGE WELLS.

GARDENS ROUND TUNBRIDGE WELLS—I.

Tunbridge Wells is not only popular among those who visit it during periods of relaxation from the sterner aspects of life, but it has become a great residential centre, and within a radius of six or seven miles there are large numbers of mansions set in gardens equally remarkable for their extent, beauty, and high keeping. There is always a difficulty in visiting a great gardening centre for the purpose of giving an account of its distinctive characteristics; but nowhere has the difficulty been greater than in this case. Time and space are limited, but there is hardly a limit to the number of good gardens. Hence many gardens that one would like to see could not be visited, and some that one had the pleasure of seeing have to be referred to more briefly than could be desired, and a goodly number of photographs have to remain, for the present at least, in the portfolio. The gardens that will be described in this and the following issue were selected with a view to include as many distinct types as possible, and thus give as it were a representative sketch of the horticultural aspects of the district.

Eridge Castle.

Chief among the numerous great gardens within a few miles of Tunbridge Wells are those of Eridge Castle, the magnificent seat of the Marquess of Abergavenny, which has been the home of the Nevills for upwards of 500 years. With reference thereto an old writer states "There is a place called Eridge Park, belonging to Lord Abergavenny," wherein, he proceeds, there is "an assemblage of all Nature's beauties—hills, vales, brooks, lawns, glades, thickets, rocks, waterfalls—all wildly noble and irregularly amiable." The description, if quaint, is apt, and conveys in a few words an excellent idea of the many beautiful features that have combined to give Eridge Castle a prominent position among the stately homes of this country. Need it be said that since Hill's time, art has combined with Nature to enhance the charms and interest of the many beautiful features, more especially those that are near the house. Among other things that have been done has been the erection of the castle, which occupies a commanding position in the park, and the creation of the wide-spreading gardens and pleasure grounds that form so glorious a setting to the grey pile.

The castle has for its setting on the south side a magnificent breadth of lawn, with numerous stately trees, of which the fine Cedar of Lebanon, and a few others, are seen in the illustration. On the eastern side, and in a position that did not come within range of the camera, is a specimen of the Weeping Beech that probably has no equal and certainly no superior in the United Kingdom. The height and spread of the branches are quite exceptional, and the contour is perfect. I have seen many fine specimens of this elegant tree, but none that can approach this, which the Marquess of Abergavenny told me was of large size when he was a boy. I shall hope to give an illustration of this beech at no distant date, and it may be of one or two other objects of special interest. On the slopes to the north of the castle there is an extensive pinetum, this being of interest for the many fine specimens of choice kinds it contains and from the fact that a considerable proportion of the trees have been planted by distinguished visitors. There is, for example, a specimen of Abies nobilis, planted in 1881 by King Edward VII., then Prince of Wales; other especially noteworthy examples including Pinus sylvestris, planted in 1882 by the late Duke of Edinburgh; Abies polita, planted in 1886, by the late Duke of Clarence ;, and Sciadopitys verticillata, planted in 1885 by the late Duke of Cambridge, and Abies Douglassi planted in 1877 by the Princess Louise.

At the foot of the steps leading from the terrace on the south side of the castle there is a spacious geometric flower garden, in which plants remarkable for the beauty of their flowers or foliage are used with good effect in giving colour to the scene. These need not be particularised, but it should be mentioned that the colouring is quiet and in full agreement with the beautiful scene in which the beds form a dominant feature. Proceeding across the lawn to the left and taking the walk that intersects the lawn, between the great hedges that form a screen to the kitchen and fruit gardens and the village of glass, and the light iron fence that separates the park from the pleasure grounds, one meets with many attractions. Here we find beds and borders, not perhaps innumerable, but in large numbers, filled with roses, hardy herbaceous plants, and other subjects of value in contributing to the attractions of the pleasure grounds. Situate midway on the walk and among great masses of dwarf and standard roses is the garden pavilion, a structure elegant in design, and with windows so arranged that those who resort to it for rest and refreshment can enjoy both light and air in such measure as they may wish. There is no gloom such as is associated with many garden houses, and those who resort to it can enjoy a book or write letters without difficulty in the matter of light, and enjoy the fresh air, so invigorating in its effect, for which the whole district is famous. They can do more than this, for the structure is so placed as to command a prospect of unsurpassed loveliness. Why garden or summer-houses should so often be placed in out-of-the-way positions, and be fitted with windows unequal to the admission of light and air is difficult to understand, but there is no difficulty in appreciating the advantages which the light and elegant pavilion at Eridge affords. A short distance beyond this structure is an especially fine herbaceous border, and in this one has, in the course of the summer, an opportunity of seeing the hardy geraniums in so high a degree of perfection as to come as a veritable surprise. It would be pleasant to pause and speak of them in detail, but the temptation has to be resisted and the brief statement made that they are all in a robust state of health, and bloom profusely.

THE GEOMETRIC FLOWER GARDEN AT ERIDGE CASTLE.

The grounds of Eridge Castle are rich in beautiful and stately trees, and to some of these a brief reference has already been made. They indeed form a great feature; and of special interest is the long line of tulip trees that arrests the attention of the tree-lover soon after passing the plant border, with its glorious display of hardy geraniums. A single specimen of Liriodendron tulipiferum, rising to a height of fifty or sixty feet, and well furnished throughout, invariably evokes the warmest expression of admiration, and deservedly so, for it is one of the most shapely of deciduous trees, and the foliage has the advantage of being at once distinct and handsome. Here there are fifteen in a row, rising to a great height, and furnished with wide-spreading branches; and as one calls to mind the impression they produced, it is not easy to speak of them without conveying the suggestion of extravagant language. The difficulty, of course, is in speaking of so distinct and interesting a feature in sufficiently appreciative terms. That it is unique goes without saying, and it is not surprising Eridge should be proud of its possession. An illustration is given herewith of the trees, and they are admirably portrayed, but necessarily the fifteen splendidly developed trees lose considerably in being compressed into about twenty square inches.

The department devoted to the production of fruits and vegetables in the open and under glass is such as might be looked for in so princely an establishment, and the judgment and skill that are brought to bear upon its management is exactly what might be expected from so able a gardener as Mr. A. Wilson. Early and late grapes, peaches, and figs are grown on a large scale in the spacious and admirably equipped houses, and in the respective seasons one may see crops that are equally remarkable for their bulk and high quality. Plant culture under glass necessarily receives a full share of attention, for only by such means could decorative plants and cut flowers be produced in sufficient quantities to meet the requirements of so extensive an establishment. In like manner cucumbers, melons, tomatoes, and early vegetables under glass are annually grown in immense quantities. In the six or seven acres devoted to fruits and vegetables grown in the open, there is an abundance of interest, and it may be said of cultural skill also, and one might refer at some length to the many object lessons they afford; but the scheme of these notes does not permit fulness of detail, and therefore this cannot be done.

Buckhurst Park.

This fine seat, the property of F. Benson, Esq., is situate some six or seven miles to the south-west of Tunbridge Wells, and, as in the case of Eridge Castle, the mansion has a glorious setting of rolling meadow and picturesque woodland. The prospect, and more especially from the upper terraces, is wide-spreading, rich, and diversified, and affords one of the finest examples of characteristic English scenery in the southern, and indeed other of the counties. At Buckhurst Park there is the added charm of water, and the large lake, with its spacious island rock garden and its beautiful arborescent fringe, forms a distinct and delightful feature. Not far distant from the present mansion is the site of Old Buckhurst, which for some hundreds of years was the home of the Sackvilles, and was one of the most important of the country houses in the South of England.

A pause might well be made to say that beautiful as were the surroundings of Old Buckhurst when the Sackvilles left it for their new home, they differed greatly from Buckhurst Park of the present day, and it might also be said that the improvements in the gardens and pleasure grounds within the past few years have been little short of marvellous. The changes have been great, and they have been such as to add enormously to their interest and beauty. Mr. Benson naturally takes a keen interest in his fine possessions, and Mrs. Benson, who takes the keenest interest in the ornamental aspects of gardening, has a wide and thorough knowledge of plants, and possesses artistic perceptions of a high order. Consequently, it may be assumed that she has taken an active part in the development of the many features that render a visit to the gardens so delightful. As one remembers the splendid accomplishments in outdoor gardening at Buckhurst Park, it is of interest to call to mind the fact that Mrs. Benson is a sister of Lieut.-Colonel Holford, and that, while the latter has been engaged in setting a splendid example to orchidists, the former has been developing, and with quite exceptional success, a garden on lines that are truly English.

THE FAMOUS ROW OF TULIP TREES AT ERIDGE CASTLE.

The mansion, a stately edifice, occupies a position in the higher parts of the grounds, and has on the north side a belt of finely developed trees, which form an excellent background to the grey masonry. On the east side, which, for the want of a better term, may be described as the garden front, is a large breadth of splendidly kept turf, with a fringe of trees its whole length on the north side, and for one-half its length on the south side. Immediately in front of the mansion is a geometrical flower garden wherein Mr. Philpott, the head gardener, provides an attractive display of flowering and fine foliage plants during the summer months. I had hoped to have given an illustration of this flower garden, and the mansion, with its creeper-clad wall, but the slope in the ground from east to west was sufficient to prevent an adequate representation of the flower garden, and portray the house in its true dignity of expression.

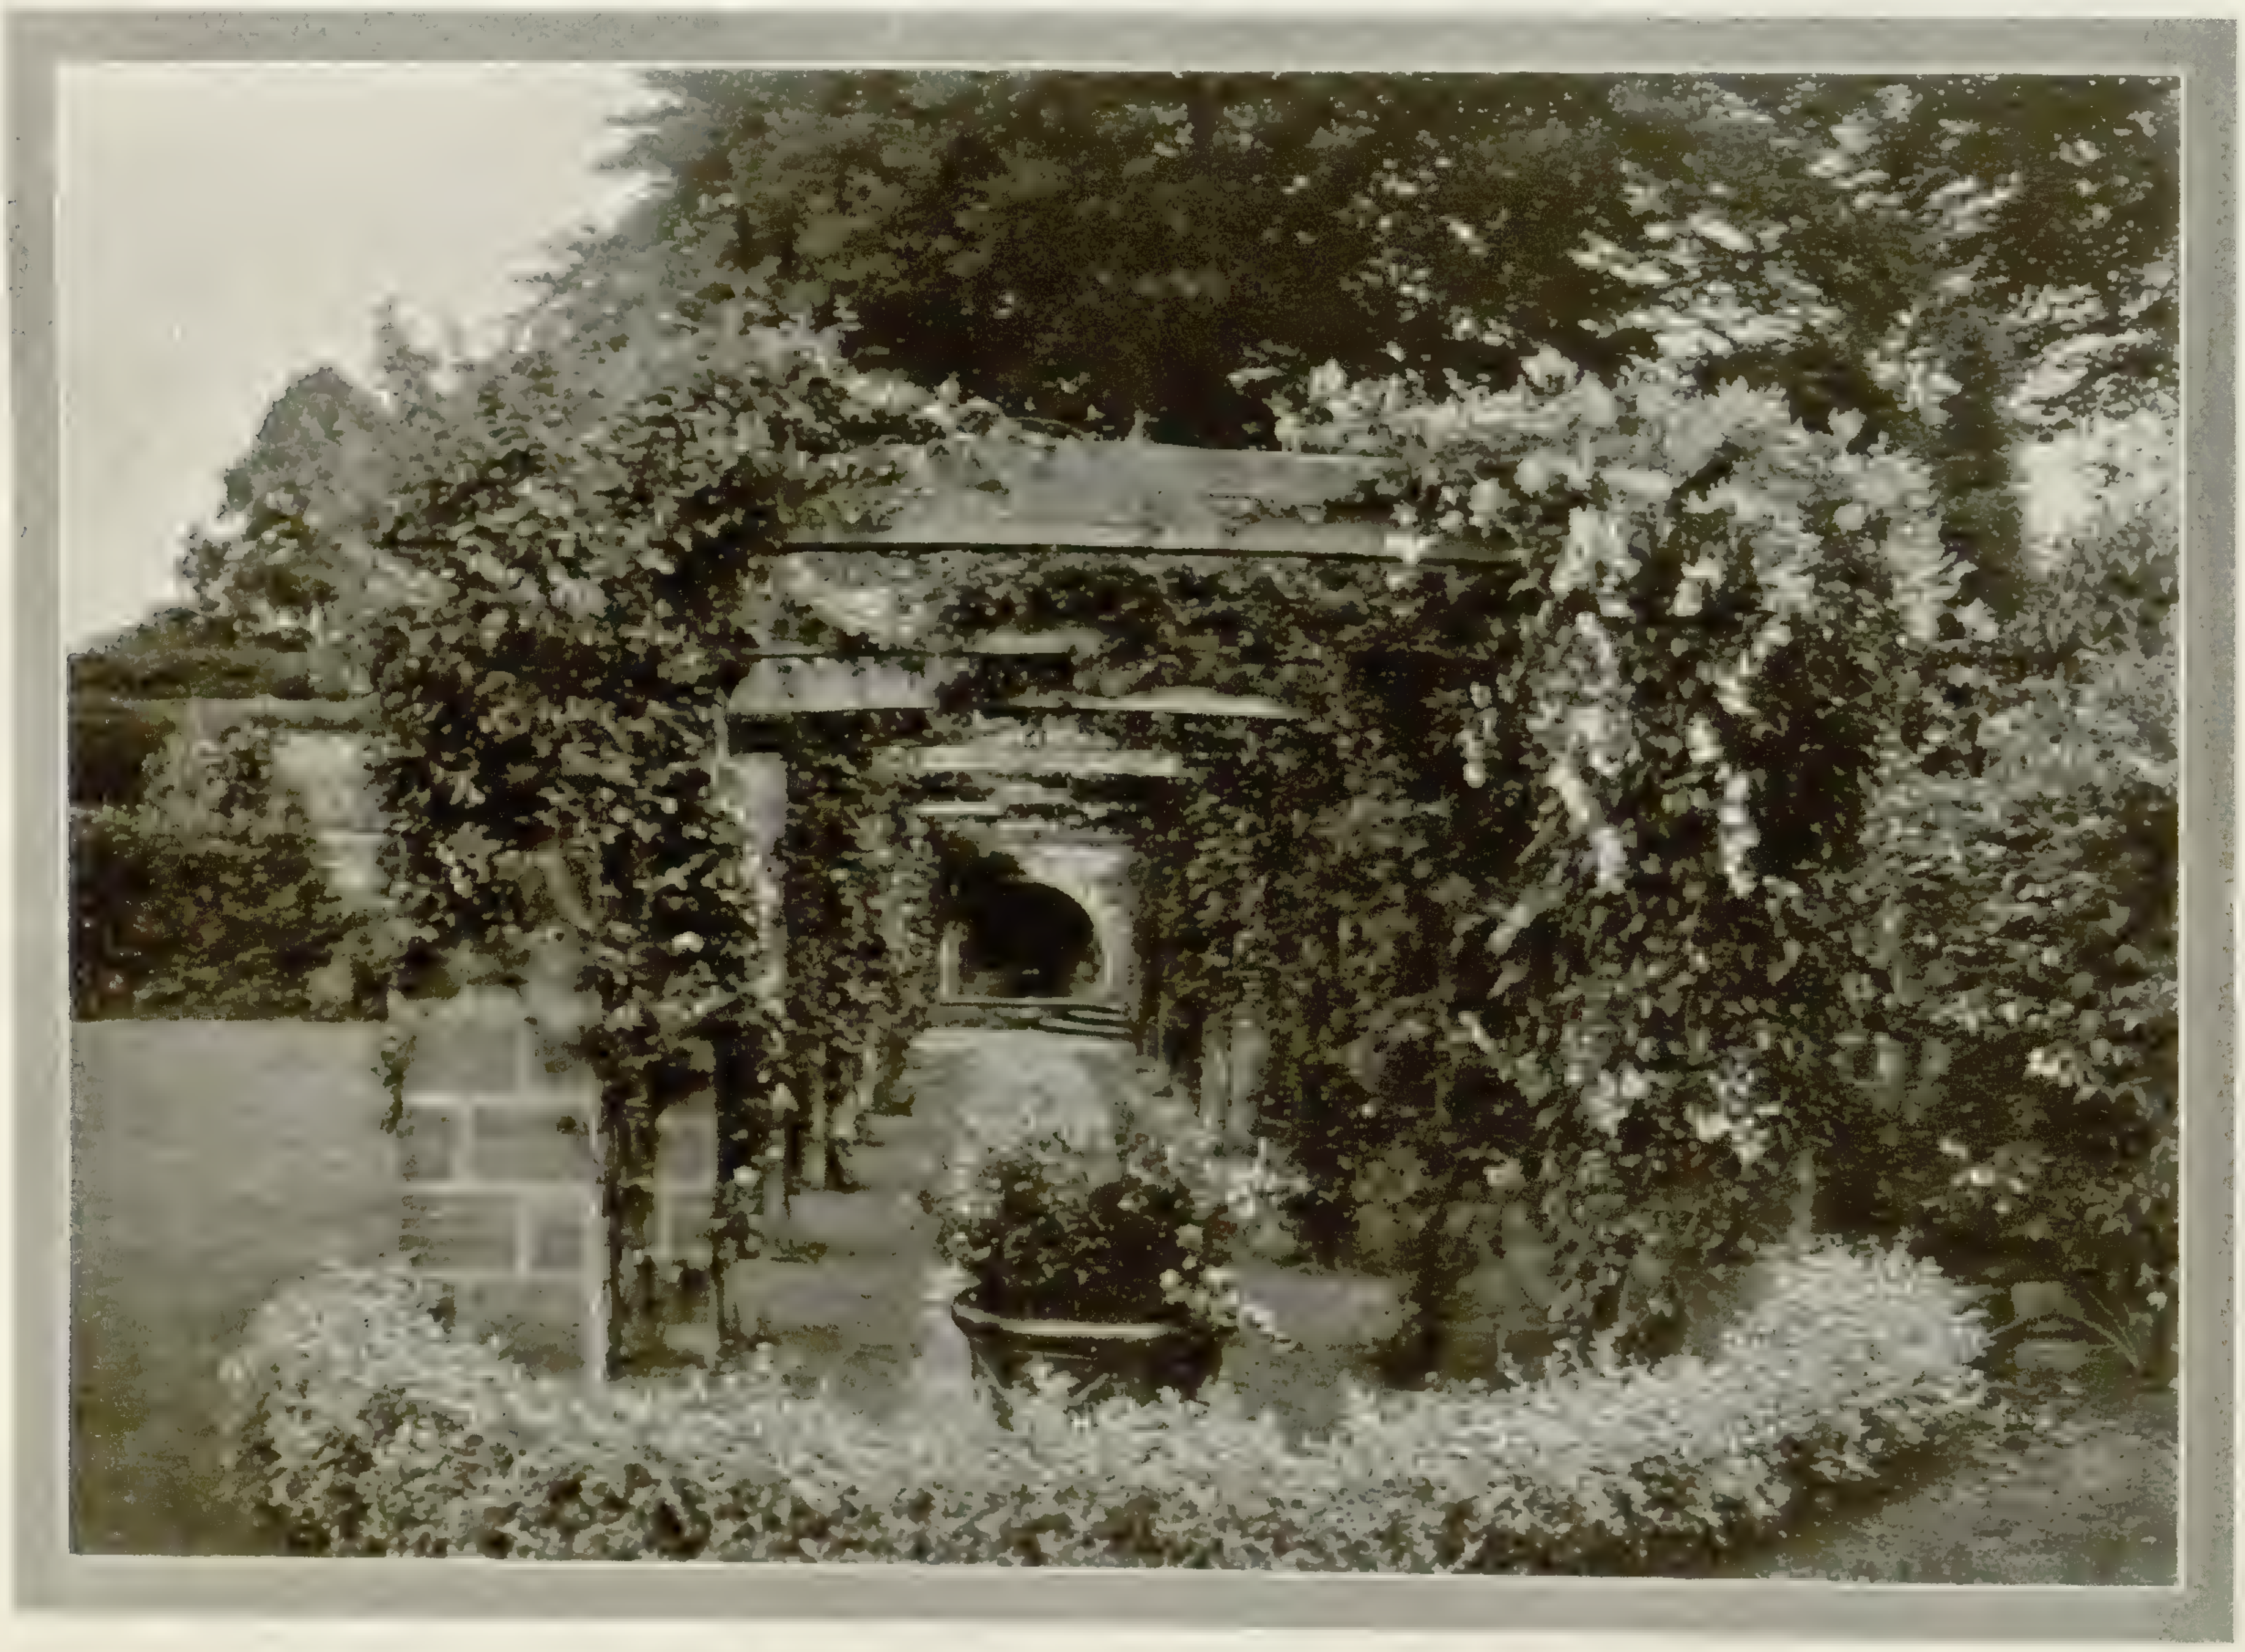
The most noteworthy of the alterations and improvements that have been made are those on the south side. Originally the ground had a continuous slope from within a short distance of the walls of the mansion to the lower part of the pleasure grounds, where they merge into the park. This slope has been broken up by the formation of two terraces, which contribute materially to the stateliness of the mansion and afford additional space for the display of rambling roses and other climbing plants, and of water lilies and other subjects of lowly growth. These terraces are strictly in keeping with the architecture of the mansion, and are supported by walls built with the sandstone peculiar to the district, and indeed taken from the lower part of the lawn contiguous thereto. The walls are strengthened by buttresses, as a matter of course of the same material, and the general effect is such as to convey the impression that the terraces, with their retaining walls have been formed for the support of the ground around the house and not to suggest, as is so often the case, that they are intended for the display of stonework of Italian design. The visitor might well be excused for supposing the terraces to be coincident with the erection of the mansion, and it comes somewhat as a surprise to be told that five years ago the stone with which their walls are built was in situ.

ORNAMENTAL VINES ON TERRACE BUTTRESSES AT BUCKHURST PARK, TUNBRIDGE WELLS.

The upper terrace is of great breadth, and has immediately opposite the mansion a large lily pond, architectural in character and of a design in keeping with the mansion and the other surroundings. Here the finest of the hybrids obtained by M. Marliac and other raisers have found a suitable home, as indicated by the robust leafage and the wealth of splendidly developed flowers that float on the surface or raise themselves above it, according to their peculiarity of growth. At the east end of the terrace, where the low wall divides it from the eastern flower garden already referred to, there is a broad border devoted to hardy herbaceous plants, and therein are represented many of the finest of the hardy perennials that now find favour in the highest state of development of which they are capable. Within a few inches of the supporting wall is a band of lavender, extending the whole length, which is attractive at all times, and especially when in bloom. A glimpse of the lavender is seen in the illustrations of the two ornamental vines growing on the lower terrace. The buttresses that strengthen the upper wall are clothed with ornamental vines and rambling roses, and those strengthening the walls of the lower terrace, of which the fountain and flanking vines are herewith illustrated, are devoted wholly to roses of the rambling type.

Rambling roses form one of the most important and certainly one of the most delightful of the many charming features. They have been planted extensively, and include all the finest introductions of recent years; they are now in the vigour of youth, and they give in their season of flowering a wealth of colour so wondrously beautiful as to surprise even those who are familiar with the flower production of the race when placed under conditions favourable to their growth. In addition to the ramblers that clothe the buttresses of the terrace walls, and are commencing to fling their elegant growths over the newly-constructed pergola, of which an illustration is given, there are large beds devoted to them on the breadth of lawn that extends from the upper pleasure grounds to the lake. These are mostly grown in standard form on stems of varying heights, and are immensely attractive in their season of flowering. With reference to the terrace roses it must be added that at the foot of the wall supporting the lower terrace a border of moderate width has been formed, and that the spaces between the buttresses are filled with dwarf roses, the selection including the finest of the several classes.

One other feature remains to be mentioned, and that is the island rock garden, which of itself is sufficient to make Buckhurst Park famous amongst horticulturists. Briefly stated, there is, in the lower part of the grounds and extending far away into the park, a remarkably fine expanse of water. This contributes its share to the general attractions, but its charm has been materially enhanced by the formation at the north-east corner, and immediately adjoining the pleasure grounds, of an extensive island rock garden. This fine example of artificial rock building is unique in conception, admirably planned, excellent in construction: in a word, is a veritable triumph. The suitability of the garden for the growth of rock plants is evidenced by the vigour of the whole of the subjects that have found a home within it. This rock garden was, I learnt from Mr. Benson, constructed by Messrs. Pulham and Son, who are so well known for their accomplishments in this form of garden adornment. On the bank opposite the rock garden are great breadths of Japanese iris that grow vigorously, as will be seen from the illustration, and annually bloom most profusely. At the north-west corner of the lake the surplus water finds an outlet, and for carrying it away, as it tumbles over the delightful fall, Messrs. Pulham have provided a replica of a Scottish burn; and they have accomplished their object so well as to prove to demonstration their thorough acquaintance with the scenery of the Scottish Highlands, and to give added charm to the grounds.



THE PERGOLA AT BUCKHURST PARK.

Ely Grange.

Ely Grange, the residence of John Waddington, Esq., J.P., occupies a position that strongly appeals to one by reason of its singular beauty; quite close to Frant, which is some three miles distant from Tunbridge Wells, and two miles or so from Eridge Castle. Unlike other of the fine seats that cluster around this old village, Ely Grange is distinctly modern, the handsome mansion representing one of the finest types of the residential building of the higher class that found favour in the second half of the Victorian era, and the grounds have been laid out in accordance with the views on the landscapist's art that obtained some thirty or more years ago. One can admire to the full great houses and gardens whose age can be reckoned by centuries when, as in the case of those around Tunbridge Wells, they are maintained in a high state of keeping. There is no difficulty in obtaining both pleasure and interest from visits to seats that bear the impress of a good old age; but it is agreeable now and again to turn to houses and gardens that are modern, but with a sufficient number of years for the appearance of newness to have worn off, and for the trees and shrubs with which the grounds have been planted to attain to considerable dimensions. To this category belongs Ely Grange, as we now know it, and if one might make a guess in such a matter, it may be said the present mansion was built and the grounds planned about thirty years ago. This suggestion is based on the fact that the grounds have been designed and planted by Mr. Goldring, the head gardener, who has had the good fortune to see his work mature and fully justify his plans, his selections, and his subsequent methods of procedure in management. Mr. Goldring has also had the good fortune, as he so freely acknowledges, of having during the long period he has been at Ely Grange, employers who have taken a keen interest in their garden, have had exceptional taste, and have given him generous support in carrying out whatever may have been considered necessary for adding to the beauty and interest of the demesne.

The grounds of Ely Grange are entered from the Tunbridge Wells side of the estate by a handsome lodge near Frant Church, and between this point and the mansion the visitor has the opportunity of seeing some excellent grouping of trees and some of the finest scenery of which the district can boast. Before, however, passing the lodge gates the visitor will be wise, if he has a taste for English landscape, to pause and enjoy the magnificent prospect obtained from near the church. The hill on which this edifice stands has a height of 600 feet, and from the church tower a fine view of the Weald of Kent and Sussex can be obtained. The mansion occupies a position on the high ground at the south-west side of the park. Around it is a large expanse of tastefully-planted pleasure grounds that forms a charming setting, affords abundant space for lawn games, and full opportunities for display of taste in the use of hardy and tender plants suitable for garden embellishment. The grounds are, moreover, of much interest for the finely developed coniferous and other trees they contain. Associated with the fine specimens of Cedrus Deodara, Wellingtonia gigantea, and abies and pines in variety are several specimens of the golden varieties of Cupressus Lawsoniana that form a fine contrast to the more sombre hues of the other trees, and greatly enhance the general effect. There are also bold masses of evergreen and other shrubs, in which the finer rhododendrons are strongly represented. Along the front of the mansion is a broad terrace with elegant balustrade and handsome vases filled with flowering plants, agaves, and other subjects. A glimpse of these is obtained in the view which includes the terrace, and a peep is also obtained of the park, with the fine lime trees on the rising ground in the far distance. The park is remarkable for its fine limes, which here attain enormous proportions.

A feature at once distinct and interesting is the great natural rock garden, which, commencing at the boundary of the pleasure grounds, extends for some hundreds of yards into the park. Originally this was a lofty bank, surmounted by trees of various descriptions, and it was evidently decided to deal with it in such manner as to convert it into a great natural rock garden.

The bank was planted with coniferous and other trees and shrubs that thrive with their roots searching in the crevices of the rock for sustenance, native ferns and hardy flowering plants that thrive on and about rock. The golden cupressus and grey junipers of columnar habit have been freely planted, and as they are in a robust state of health they are brightly coloured, and produce a rich effect in contrast with the dark green foliage that forms the background. An irregular pathway is taken through the garden, and here and there are open spaces, in which hardy plants not so well able to battle with strong growing neighbours have been given a home in which they thrive and produce a series of charming pictures.

Of the departments devoted to the production of flowers, fruits, and vegetables there is no occasion to speak. It may, however, be mentioned, as a point of special interest, that Mr. Goldring has a high opinion of standard gooseberries, and that the prodigious crops they bear fully justify his views with regard to their usefulness.

GEORGE GORDON.

THE ISLAND ROCK GARDEN, BUCKHURST PARK.

A FAMOUS GARDENING VILLAGE.

Several years ago Mr. Norman C. Cookson, of Oakwood, Wylam-on-Tyne, well known to readers of these pages as a great orchid enthusiast, told me of the great interest taken in gardening matters by the miners in some of the villages of Tynedale. He specially referred to Prudhoe as being a great centre of horticultural activity, and as he told of huge bougainvilleas, statices, allamandas, rondeletias, stephanotis, and the like, and of the wonderful carrots, leeks, and beets, and the fine dahlias, asters, marigolds, etc., produced by the miners, my interest in this Tyneside village grew, and I determined that some day I would visit Prudhoe and West Wylam, if the fates were kind.

Further back than the date of this particular conversation I had seen excellent stove plants at Newcastle Show, but did not realise that many of them were grown by those who gained their living deep down in the mines. But Mr. James Hudson, and my friend Mr. H. J. Chapman, both assured me that these fine examples were grown without any professional assistance, and in houses built by the men themselves, and that they were tended by wife or daughter when the good man was working his shift. So it came about that during last autumn, when on a business trip to the Newcastle district, I paid a visit to several of the most famous growers in the mining villages of Prudhoe and West Wylam, in the company of Mr. H. J. Chapman, who is an "exceeding great" authority on every gardening subject with these enthusiasts.

Every miner has his cottage and a good-sized plot of ground at a nominal rent, and though very few neglect their ground entirely, the degree of interest and enthusiasm possessed by the holder was written plainly across each garden. The gardens are in batches, and you may look across some sets and wonder whether or not every other person is a budding market grower, for the sunlight glistens on scores of glasshouses and hundreds of frames, and upon brilliant patches of florists'. flowers amid which "protectors" are very evident. There is one weak point about the gardens of this district, and that is in comparatively few of them are the flowers, fruits, plants, and vegetables grown for home use. There is a strong sporting instinct in these hardy Northumbrians. They are fighters, too. Perhaps there still remains some of that spirit which pervaded the districts in the old days, when moss troopers and border raiders might swoop down at any time, and when it was often excellent policy to carry the fight beyond the old Roman Wall into the enemies' country. But the fighting nowadays is done with plants or flowers, and in the show tent. The value of the prize does not seem to matter very much to these good people, but the winning of the prize is everything, and no pains are spared to secure it.

I imagine that Prudhoe (which includes West Wylam) has more keen horticultural exhibitors for its size and population than any other place in the United Kingdom. If there is a place can beat it I want to know where it is. The Prudhoe Floral and Horticultural Society has about forty patrons and patronesses, its president and vice-presidents include the leading gentry of the district, and its committee of thirty-seven members is a hard-working one, drawn from among the men themselves, and most of them are miners. The chairman of the committee is Mr. Walter Telford, and he has occupied the position for a long number of years, and has received several handsome tokens of the respect in which he is held by the members, and evidence of the high appreciation they have for the services he renders. Everyone knows "Walter," as he is familiarly called, and his opinion and decision are eagerly sought when knotty points of culture or procedure come up for discussion.

TERRACE GARDEN, ELY GRANGE, TUNBRIDGE WELLS.

Let us peep into Walter Telford's garden. There is no waste room, and the paths are for lean men rather than for fat ones. Just inside the high, well-locked gate is the shed filled almost to overflowing with horticultural impedimenta. Here is a stand of choice flowers, stove and greenhouse kinds, that won first prize somewhere in the district yesterday, and here the dozen roses that missed the premier award by about half a point, and hard by are the remains of sets of exquisitely marked French marigolds, and of fine quilled and Comet asters, that the southern counties would find it hard to match. Mr. Telford's son pulls out some superb leeks from under the potting bench, both "pot" leeks (short thick-stemmed ones), and long leeks, the latter having size and finish that even a Beckett or a Gibson would hardly beat. These, and some wonderful carrots and beet, are quickly wrapped up, and put away for a show a day or two hence, and Mr. Telford, jun., then shows some examples of his skill as a florist, and it is no mean skill either, as many a professional knows to his cost on the show board, and when there is a wedding at Prudhoe, young Telford is in great request for bouquets and floral favours.

What are these deep, frame-like arrangements? They are the deep beds of fine rich soil in which are grown the exhibition carrots, leeks, beet, parsnips, and celery. Boarded up 2½ft. to 3ft. deep, these beds produce wonderful material, and to fill them with the best soil loam is carted long distances. There is no chance work at Prudhoe, for that would mean no chance at all at exhibition time. There are some wonderful stocks of leeks in the village, and leek clubs are a great institution. Most of the successful men keep up their own strain, and not seldom two or three leeks, for stock purposes, have changed hands at 10s. each. They do not mind spending money, these good people, but when they ride a hobby they must have the very best it is possible to obtain.

Farther on are the plots of African and French marigolds, dahlias, roses, gladioli, asters, antirrhinums, and other florists' flowers, all regularly set out, and allowed ample room, but in no sense arranged for effect. Here are frames and handlights, so useful in springtime, and at the far end of the garden is a glasshouse, of quaint design, and well heated. It contains ferns and asparagus in abundance, begonias of sorts, a bougainvillea, and a few oncidiums and cypripediums, besides many other things; but Mr. Telford is not a specimen plant man, his efforts are chiefly devoted to the vegetables and florists' flowers already noted. We leave Mr. Telford's garden, but not until we have promised to return to his house for tea, a promise we fulfil presently, to Mrs. Telford's great delight, and our own great satisfaction. A Northumbrian miner's "tea" is like a Yorkshire tea, only more so.

Another Prudhoe worthy is Mr. R. Arthur, a tall dour man of few words. His garden is almost covered with glass, all built by himself, and heated with a heating apparatus made and designed by himself. He has three good-sized plant houses, cool, warm, and intermediate, and his great hobby is the production of big specimen plants. My visit was untimely, as a dozen of the best plants were away from home, winning prizes for their owner. I am not going to be so foolish as to say that Mr Arthur grows specimen plants that would make Mr. John Cypher turn tail at Shrewsbury Fête, but I assert, and very deliberately, that Mr. Arthur's best half-dozen would not feel ashamed of themselves if they stood in the company of the Cheltenham specimens. Stephanotis floribunda, Rondeletia speciosa, Allamanda Hendersoni, Bougainvillea glabra, statices, Clerodendron Balfouri, and Dipladenia amabilis are the great stand-byes, and they are 3ft to 4ft through, and as much or more in height, and grandly flowered. Kentias, heliconias, and marantas, with Asparagus plumosus, and various adiantums provide the foliage plants, and some of the latter are especially good. Lapagerias, pelargoniums, and fuchsias fill the cooler house, while in the several houses are to be found a number of orchids, notably Cypripedium insigne, a C. Curtisi nearly two feet across Cœlogyne cristata, and Oncidium flexuosum. Not a bad list for a hard-working miner, eh?

Further along the village we visited many another garden, and one thing that struck me was the courtesy of these competitors. Every gate was open for Mr. Chapman and myself, but our guides would not think of entering unless invited, or they had asked permission. In one case the owner was absent, but the gate was opened for us, and promptly shut behind us, but we made the inspection of beautiful dahlias and gladioli, excellent fruit, tomatoes, and leeks, all alone—the others, possible competitors, would not enter, but they knew that the owner would feel very disappointed if we failed to see his crops

But I must close these notes, for the present at any rate, and close with a story told me by Mr. N. C. Cookson. Some time ago it was found that several of the miners were using more than their recognised share of coal for household use, and investigations showed that those who had exceeded the allowance were the men who had glasshouses in their gardens. The coal was being used for the hobby, not for the home alone; this must be stopped. The matter was brought before the board meeting, but Mr. Cookson asked that before any definite step was taken the overseer should submit a chart showing the amount of time worked, the amount of time lost, and the amount of coal worked by the miners. This was drawn up, and it was found without exception that those who had used rather more coal than the usual allowance were all enthusiastic gardeners, and that these men were the best timekeepers and the best workers. In other words, the garden beats the public-house as an attraction for these sturdy miners. Why? Because the garden appeals to all that is best in heart and brain, and brings out the skill of hand and eye.

CHAS. H. CURTIS.

POPULARITY OF FIGS.

The popularity of the fig—or "green fig"—is undeniable. And it may be taken for granted that this popularity is increasing, and deservedly so, for what more luscious morsel can anyone require than a well grown and thoroughly ripened fig, provided always, of course, that it is of a good variety? It will be thought from this latter remark that there are good and bad varieties; but without going so far as to say that any are really bad, one may say that some varieties are not nearly so good as others, and even those generally considered good depend largely for their success upon how they have been produced, and how nearly they are to being thoroughly ripe when picked.

To have a fig in the pink of condition it is necessary to exercise some care in selecting it, as an unripe fig is nauseous, and quite unfit to eat. When a milk-like juice is seen to exude from the end of the stalk one may be sure that fig is not ripe, and should have been left for a few more days. When a fig is perfectly ripe it will have fallen over a little, while a large, bright globule of juice, called a "teardrop," will stand in the eye, and the skin will have slightly cracked, in streaks.

The fig is a native of Syria, and is at home on the shores of the Mediterranean, and is, in consequence, except for a few very favoured localities, unsuited for outdoor culture in this country. Although with the protection that a wall affords the fig may be grown anywhere as an ornamental plant, yet, if fruits are desired, it is necessary that it should be grown under glass, either in pits or houses, which may be either lean-to or span-roofed. Figs may be planted out and trained over walls or wires, or grown in pots. Pot culture is the method I recommend, as by this means the plants are very much more under our control, and those planted out generally grow too strong to be very prolific.

The fig has one quality quite peculiar to itself, and, so far as I know, a quality which does not apply to any other fruit, and that is, it will bear two, and sometimes, under favourable conditions, three crops in one year, but, of course, that means beginning early. Even those who do not happen to have the best of conveniences at disposal, and can only afford the shelter of a cool house, may with proper care be sure of one crop each year. This, to my mind, is a great consideration, and ought, if generally known, to help forward the popularity of the fig.

With regard to soil the fig cannot be said to be very particular; planted out, it will thrive in any good garden soil containing a fair proportion of lime rubbish to make it porous, but for pot culture it will require a somewhat more liberal material. A compost I have found to give good results is one of three parts good loam, and one part lime rubbish, with a few half-inch bones, some wood ashes, and a little well-rotted stable manure. The pots should be well drained, and the soil firmly rammed. It will be necessary, while the plants are growing, to give several top-dressings, which should be of a rich nature, such as a good fertiliser, one containing bonemeal and horn shavings for preference.

Attention to the watering of figs growing in heat is of the utmost importance. If they have been properly potted, and have a free drainage, it will be rather difficult to overwater them during the growing period, and they should be syringed two or three times a day, keeping the atmosphere of the house always moist. If care is taken to shut up early, and conserve sun heat, it is only on dull days and at night that they will require any fire heat.

VIEW IN ROCK GARDEN, ELY GRANGE.

As the fruits reach the ripening stage it will be necessary to reduce the water supply at the roots, and to keep a much drier atmosphere; overwatering at this stage will have the effect of spoiling the flavour of the fruits, while a too humid atmosphere will cause them to split open before nearly ripe. When the shoots have grown four or five inches long they should be stopped by pinching out the growing point; by this means the plant will be induced to push out the fruits, which lie dormant in the axils of the leaves, and too strong a growth is prevented, which saves much after-pruning, and preserves the points of the shoots on which the first crop of figs will be formed for the following year.

The temperature while the figs are making their growth may be, so long as it is a moist heat, from 75 degrees to 90 degrees, and may, with sunshine, run up to as much as a 100 degrees or more, but care must be taken that the plants do not suffer for want of water, or the foliage will flag and burn, and cause a certain amount of disfigurement, and burning is not a sign of good cultivation.

And now with regard to attacks from insects. While the plants are healthy, and kept in a good "growing" condition, there will not be much to fear. Sometimes mealy-bug is rather troublesome, and it should be looked for, and got rid of as soon as it makes its appearance. It may easily be destroyed by examining the plants and touching each individual insect with a small stick which has been dipped in methylated spirit. Red spider and thrips are other pests which have to be dealt with at times, but will quickly disappear under a clean water treatment frequently and briskly applied with the syringe. A more difficult subject to deal with, however, when it makes its appearance, is a small white scale, which adheres very stubbornly to the wood and leaves. Not much can be done for the eradication of this pest while the plants are growing, but it must be dealt with in the winter, when the plants are in a dormant state, and may be scrubbed with a fairly stiff brush, such as a nail brush, with a solution of soft soap or some other good insecticide. It is very important that every bit of it should be killed, for it spreads very rapidly, and will soon infest the whole of the stock.

In giving a short list of varieties—I think a dozen will be enough for all practical purposes—I shall only select those that are of first or medium quality, and are generally recognised as good croppers, as this will enable anyone desirous of growing figs to make a selection, which, if properly managed, cannot fail to give good results.

Bourjassote grise.—This I consider is one of the best, if not the best, of figs in cultivation. The fruit is of medium size, rather flattened in shape, with deep red flesh, and very luscious flavour.

Brown Turkey.—Fruit of medium size and quality. This variety should be selected by those who wish to grow figs in a cool house.

Brunswick.—The fruit of this variety is large, and long in shape, and of medium quality. Another useful variety for cool house.

Col. di Signora Bianca.—Fruit of medium size, with red flesh, very rich in flavour.

De l'Archipel.—Fruit rather above medium size, flesh pale, juicy, and rich.

Gourand Noir.—Fruit medium size, dark purple skin, flesh red and rich.

Monaco Bianco.—Fruit rather above medium size, green skin, red flesh, and very rich. This variety is almost equal to Bourjassote grise.

Negro Largo.—Fruit large, and long in shape, with red flesh of medium quality.

Nebian.—Fruit very large, deep green skin, bright red flesh, and very rich.

Pingo de Mel.—Fruit large, with yellow flesh that is very sweet and juicy. In some cases this variety requires judicious thinning.

St. John's.—Fruit large, with very pale flesh that is sweet and very rich.

Violette de Bordeaux.—Fruit medium size, dark purple skin, flesh red and sweet, of medium quality.

Anyone who has room for it should grow a plant or two of White Ischia. I have not included it in my list because the fruit is rather small; the flesh is pale, tinged with red. It is an enormous cropper, and delicious in flavour.

Chelsea. T. W. TURNER.

Grafting.—Apple and pear trees in a healthy state, but producing fruit of an inferior quality, may be brought into a more useful condition by being grafted during the proper season with a better variety. Prunings for this purpose should be reserved now, choosing clean, healthy shoots of last season's growth; tie them up in small bundles properly labelled, and heel them in the soil on a north border. In very severe weather, cover lightly with some strawy matter. Trees to be grafted may have their branches shortened to within a few inches above where the scions are to be inserted, but care must be taken not to damage or tear the bark in the process.—GEO. WOODGATE, Rolleston Hall Gardens.

LATE SINGLE CHRYSANTHEMUMS.

We remember the late single-flowered chrysanthemums more especially in connection with varieties that came into blossom in late November and early December. In what was described as the "mid-winter show" of the National Chrysanthemum Society these late singles were often represented in beautiful character and pleasing form. It was in this way that growers came to appreciate the flowers, and realise their great possibilities. This was some years ago. Within the interval of time that has since elapsed, development in the single-flowered section has been nothing short of remarkable. The flowering season is no longer confined to a short period towards the close of November, for from August until the closing days of the year the dainty blooms of the single-flowered chrysanthemums are always now in evidence.

Older florists, with few exceptions, saw little that was commendable in the singles in the earlier days. At that time compliments were seldom heard respecting any of the newer varieties as they came into notice, and the wonder is they ever came into public favour at all. Fortunately, there were men who could fully appreciate the decorative worth of the single chrysanthemums, and they meted out their praise in no uncertain terms. As opportunity offered these flowers were set up in many forms of indoor decorations, and so pleasingly did they associate with the heavier-looking double flowers, that their value as decorative material became increasingly apparent. Sprays of blossoms, cut with long, erect stems, may be disposed in large vases, bowls, and numberless other receptacles with the greatest ease. The more dainty sprays make charming individual decorations when set up in the smaller specimen glasses that are numerous in most homes, and we doubt whether their blossoms are regarded with greater favour at any period than the few weeks immediately preceding the festive Christmas season.

At the time of writing we have the singles charmingly represented in several rooms of the house, and in no position do they seem out of place. Their uses are many and varied. At one time it was argued that these flowers did not last well, but in my experience they last quite as long, and, in certain instances, longer, than many of the double-flowered ones. Quite recently, after the lapse of a month, we discarded singles that had done duty three days at the Crystal Palace in November, and were brought home after the event. We have now (December 16), still looking quite bright and beautiful, a goodly number of singles that were shown about a fortnight since, and we have little doubt we shall keep the flowers until after Christmas. By changing the water pretty frequently, and by cutting off a small portion of the stem of the flowers from time to time, they are made to last several weeks.

But it is my endeavour in the present instance to call more especial attention to the late-flowering singles, in the hope that some readers who have not yet come to realise their real worth may, perhaps as an experiment in the first instance, take in hand a small selection. I do not admit that all the late-flowering singles are perfect specimens of their kind, for many of them develop several rows of florets, which the older florists regard unfavourably. There are plenty of good singles, however, quite true to type, that are less pleasing and fascinating than others of a lower standard of quality. After all, it is their decorative worth that we learn to appreciate, and if this be kept in mind by the raisers of these flowers, the single-flowered chrysanthemums will continue to gain in popular esteem.

The propagation of late-flowering singles should not begin too early. There is, unfortunately, a too feverish haste to commence the work of another season. A period of rest is desirable for most plants. I pin my faith to the propagation of late kinds in late January at the earliest. As the days begin to lengthen the new growths appear to possess the necessary vigour to ensure a satisfactory start being made. The rooting process, too, is far more satisfactory at this time than in the dull, miserable weather of a month earlier, so that the prospects are better in every way. This propagation of the late singles may be continued for several months, so long as good clean cuttings are procurable. The chief advantage of the earlier propagation, so far as I have been able to determine, is that larger plants have been produced. If the plants be pinched when they are some six to eight inches in height they will quickly break into growth, and the foundation of a bushy specimen be thereby laid. I make a rule to pinch each succeeding six inches of growth in similar fashion, and when this is continued for some months, and the last pinching carried out about the middle of July, beautiful specimen plants of a bushy character invariably result. The plants should be grown on to the terminal buds, and the more crowded buds in each spray partially be thinned out. Should large, handsome, and especially attractive flowers be desired disbud to one bud on each shoot, and the result will be all that one could well desire.

It is astonishing what some plants will do when treated in this manner; they will yield a wonderful display, that should be especially valued either as plants for conservatory embellishment or for providing a supply of cut flowers throughout December. Cool, or fairly cool treatment under glass is absolutely essential, otherwise the plants will come on with a rush, and disappointment ensue. Just a little more warmth as the buds begin to unfold is desirable, as this assists them at a crucial period, and also helps to dispel damp.

Highgate. D. B. CRANE.

(To be continued.)

PEACHES OUT OF DOORS.

It does seem strange to those who grow really fine peaches on outside walls to hear that peach culture in the open is a lost art, and that the climate of this country has so changed during the last twenty years that glass is an absolute necessity to enable gardeners to present decent fruit to their employers. Some employers also believe that there has been a change, that they agree, and find the necessary glass equipment.

It is a pity such sceptics could not see the peach wall at West Dean Park, Chichester, under the management of Mr. Smith, who smiled at the suggestion I made to him last August, that peaches in the open were a failure. He pointed to a tree of Royal George growing against a south wall, from which they had just previously taken 300 fruits, and by the healthy appearance of wood and leaves, the prospect for next year was equally good. Such trees not being devoured in their early stage of growth by black and green aphis, and later with red spider, have nothing to interfere with their growth, and are able to obtain all they require at the right time. Not so with the trees under the charge of those who complain of the unfitness of wall, soil, and climate. Such grumblers are to be met with almost daily. Alexander Noblesse was another variety pointed to as being a huge success. S. H.

GARDEN ROOT CROPS.

The vegetable crops we grow in gardens and term root crops usually also comprise those with swollen stems, such as the turnip, kohl rabi, celeriac, etc. The greater number of the kinds most commonly grown for consumption are called upon to develop their more important parts below the surface of the soil. This being the case, it will be a matter of some importance to take into consideration the soil, position, and the crop previously removed from it.

If the ground intended for the strictly tap-rooted kinds is vacant during late autumn that will be an advantage which the thoughtful cultivator will not pass by. The greatest advantage to any soil accrues when it is as fully exposed to the elements as possible during the winter months; apart from the weathering influence upon the soil, it is detrimental to insect pests that do great harm to root crops during the summer months, more especially in old gardens where the soil is very rich in organic remains. Rich soils of the class named are fine preserves for the troublesome small pinkish millipedes, and the deadly wireworm; these pests are always devouring vegetable remains or the choicest roots, so that the richest soil in the garden is not the best place for the production of the best tap roots. Humus collects quickly in well-manured low-lying gardens, where drainage is slow, and unless a little lime is used occasionally to rectify the vegetable acids, good crops and clean healthy roots cannot be produced. Anyone having had charge of a garden for a short time will be able to so arrange his crops that those of a tap-rooted character following them will not require the aid of farmyard manure. For such roots as salsify and scorzonera very poor soil will produce more serviceable roots than any other. Salsify is especially addicted to making side roots that detract from its value for market or home use. Not unfrequently root crops in gardens are coarse, but coarseness does not always lie at the door of a rich rooting medium. There are other important points to bear in mind if the highest points in each kind are to be emphasised. Too early sowing of some roots that are intended for late autumn, winter, and spring uses, will result in overgrown produce. Also a highly selected strain, especially of beetroot, is a necessity, if uniform quality is desired.

The most suitable ingredients to add to well-worked soils for spindle and tap-rooted vegetables are, according to the texture of the soil, burnt earth, wood ashes, soot, salt, lime, or, in extreme cases of tenacious soils, old sifted potting soils will lighten and thus warm by greater aeration soils of this character. Forming raised beds on cold soils is also an advantage, more especially when earliness is an important point, whilst on very shallow soils, the same principle holds good in giving a deeper root range. The various ingredients named as being good for root crops usually serve a double purpose. Lime is disliked by insect life, and is often of value to plant growth by liberating locked-up food. Soot helps to attract greater warmth from the sun. Insects dislike it, and it also contains food for stimulating growth. On dry soils salt conserves moisture, is disliked by insects used in the case of beetroots and carrots, and the roots usually turn out much brighter and clearer in the skin. Kainit will practically answer the same purpose for these crops. Anything that has passed through fire, in the shape of prunings, burnt rubbish, and clay are also avoided by insect life. Generally speaking, the spring is the best time to apply any of the things named, lightly forking them into the surface; forking may not be necessary in every case, especially if the surface is very rough, simply spreading and patting down to a level with a large rake will answer the same purpose.

Garden soils generally vary very much in texture, and a large share of practical knowledge must be exercised in working them. If it is not possible to work land in the winter for them, because of such crops as borecole, broccoli, or sprouts occupying it, no one need despair, only in this case there will be no winter frosts to break up the particles of soil, so that the spade or fork must do that part of the work, and thoroughly, too. Small spits are advisable when turning over, and a sprinkling of soot on the face of each trench will do good at these spring preparations. Napiform roots will succeed better in soil well manured; the manure must not, however, be immediately upon the surface, it must be decayed and be sufficiently far from the surface to attract moisture, conserve it and have that cooling effect upon the soil that is so valuable during hot, dry weather. It is necessary in these cases that a portion of the soil upon the surface should be sufficiently firm to induce the swollen part necessary for food being properly developed. If the soil in these cases is rich, loose, and light, too much leaf growth will develop, and at the expense of the edible part required.

Some of our smaller and highly selected stocks of carrots have been so carefully tended for years as regards shape, colour, and uniformity to type, that they may be relied upon, being such small rooters, to revel in almost pure decayed humus, and under such conditions they develop quickly, are of good colour and excellent quality. Of all tap roots grown in gardens, the carrot suffers most in having one or two fixed dates for sowing, instead of commencing in March in the open and continuing to July for a succession of young sweet roots. All the root crops grown succeed better in an open position in gardens, excepting turnips, during the hottest summer months, and during that time kohl rabi is superior to hot stringy turnips. The finest quality in turnips is usually those from July and early August sowings in open positions. Unless good frames are to be had for early crops, April sowings in the open are usually of good quality unless the spring is a very ungenial one, and in that case flower stems appear early and many of the plants are useless. The points that must be considered to be successful are: thorough and deep digging, careful preparation of the seed bed under favourable conditions, the proper solidity accurately gauged according to texture of soil, thin sowing, early thinning, and proper aeration by hoeing, preventive measures for leaf miners, aphides, and underground pests. These few things kept in view will usually bring desirable returns.

CHARLES FOSTER.

Cyclamens are exceedingly useful for furnishing vases and ornamental receptacles indoors during winter and spring. The foliage is always refreshing, particularly when the leaf variegation is well developed, and the flowers are frequently pressed into service to supply the demand for cut flowers for the lightest glasses. Some assistance from artificial manures at this season will enable the plants to produce finer flowers over the maximum period, as to unduly strain them in the earliest part of the season adversely affects the latest flowers, and unless timely nourishment is provided these will inevitably be small and poor.—THOMAS SMITH, Walmsgate Gardens, Louth.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

SEASONABLE NOTES.—Up to the time of writing, we in the North of England have had very little cold weather, and have practically reached the turn of the days without having to resort to excessive fire heat. This, generally speaking, cannot fail to be beneficial to orchids. I consider that excessive fire heat is more detrimental to them than anything else. This is especially the case where the heating arrangements have not been sufficiently considered. Estimates are usually made with the best intentions, and at the lowest possible cost; but frequently the apparatus is not sufficiently powerful for the work it has to do. I wish a few more gentlemen would consider this most important matter from the same point of view as that from which my employer, Mr. Norman Cookson, considers it. The scientific, as well as the practical, from the combustion of the fuel to the air valves, and with the aim in view of supplying heating surface sufficient to provide the necessary temperatures without having to unduly drive the fires, and having the unsavoury smelling pipes, which, in the usual course, necessarily follows insufficiency of piping in the houses. It is for the owners and their gardeners to decide the amount of piping to be supplied with every structure, and a proper system of heating should be one of the first considerations. With plenty of boiler power and heating surface, the pleasure of working is not the only consideration, but it may be looked at from the point of economy in fuel also, which means a great deal in considering the initial cost.

BLINDS IN WINTER.—Dispense with as much fire heat as possible is generally advocated by orchid specialists, and there are many simple appliances that may be brought into use with this end in view. Where lath roller blinds are fitted to the houses, I consider that one of the chief advantages of their use is as a protection against cold winds and frosts in winter; but we have to be particularly careful to prevent their being snow-laden. A few mats sown together and rolled along the roof prevents to a great extent the eaves becoming frozen, and if coverings of this description can be raised slightly above the glass, so that a current of air can pass between, they are found to be more beneficial still. Where the houses are erected with side lights a considerable advantage will be found in suspending a covering from the gutter downwards, old and disused blinds work in to make useful coverings for this purpose. I would advocate in all cases the brickwork being carried to the roof.

CLEAN GLASS.—Keeping the glass clean is another important point at this season of the year; any obstruction to the light at the present season is detrimental to the well-being of the plants. In the neighbourhood of London, and other large towns, the work entailed in keeping the glass clean is very considerable, where fogs are so prevalent; even under more favourable conditions we find it desirable to devote considerable time to cleansing the roofs.—H. J. CHAPMAN, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

PREPARATORY.—Now that the Christmas season is over, with its attendant drain on the resources of the plant houses, etc., one's thoughts naturally turn towards the requirements of the year on which we have just entered, and as our seedsmen have plentifully supplied us with catalogues, it may not be an unwise proceeding to make a few notes of the various seeds required to help us in making the conservatories and greenhouses gay during the year. Those who want a succession of bloom during the season, often from a minimum of space, cannot do better than grow a goodly number of these subjects that are raised from seed each season, flowered in a few months, and thrown away, thus making room for their successors. A selection from the following might be made: Browallia speciosa, begonias, double and single, calceolarias, campanulas, carnations, celosias in variety, Clerodendron fallax, cinerarias, celsias, cyperus, cyclamen, Francoa ramosa, gesneras, gloxinias, humeas, Lobelia tenuior, Medeola asparagoides, mignonette, nicotiana, primulas in variety, rhodanthe, saintpaulia, Schizanthus pinnatus, S. Wisetonensis and retusus, torenias, and Trachelium cæruleum.

SEED SOWING.—It is yet full early to sow seeds of any sort, and by leaving the sowing till, say, the third or last week in the month, with the lengthening days the seeds germinate more quickly, and the seedlings make a stronger growth. It will be wise to see that all the bins (under cover) are filled with loam, leaf-soil, peat, sand, etc., so that when the time arrives all material will be to hand in good condition. All pots, pans, and boxes should be cleaned, and stored in their sizes, the occasional wet days providing the means of having this done by the outside men.

PREPARING FOR SPRING.—As previously mentioned, during the past week or two the resources of the plant houses will have been heavily taxed, and a great many of their contents used in the decoration of the conservatory and indoor apartments. Before refilling with bulbs and forced plants they should have one of their periodical cleanings, and for this purpose everything movable should be taken out of the house, and all shingle cleared off the stages.

CONSERVATORY.—At this season of the year plants should be as lightly disposed as possible in the conservatory, whether it be in groups on the ground, or on stages, allowing as much air as possible to circulate between them, thus helping to prolong the flowering period. Air should be admitted on all favourable occasions, with enough artificial heat to keep everything warm and dry, especially in the cases where the doors open into drawing-rooms. All dead blooms and decaying leaves must be rigorously removed, and everything done to maintain a clean and tidy appearance.

FORCING PLANTS.—Continue to take indoors weekly batches of bulbs, shrubs, and other plants for forcing, to maintain a regular supply of flowers in the conservatory and for the supply of cut flowers. Choose kinds that are naturally early blooming, and the later kinds for successional supplies. Freesias that are producing their flowers should be staked, and placed where they will have a little more heat, giving them occasional supplies of weak liquid manure.—THOMAS STEVENSON, Woburn Place Gardens, Addlestone.

THE FLOWER GARDEN.

PROTECTION.—Although we have had an extremely mild autumn, and, indeed, mild weather until the time of writing, it frequently happens that we experience much colder weather early in the New Year. It will therefore be well to make every provision in case of necessity. Many of the most beautiful half-hardy flowering and foliage shrubs may be safely brought through the severest winter if a timely protection is afforded them. There are many means and ways of accomplishing this. The roots and the base of the plant should receive first of all a good mulching either with long litter, or better still, dried bracken. The same material may be added for protecting the plants generally, and if they are not too large the more tender may be enclosed entirely with mats. Small specimen plants, creepers, and such like should be treated in this way. Fresh cut spruce boughs make admirable protection and shelter for plants growing on pergolas and open fences.

ROSES.—These also should have careful attention at this season of the year. Many of the beautiful teas and hybrid teas, especially when grown in bush form, can be protected from severe weather by applying a good covering both to the roots and growth, of either long litter, straw, or bracken. Standards and half-standards of the more tender varieties should be protected by tying a reasonable amount of clean straw well over the heads.

WATERSIDE PLANTS.—Many of these, although practically hardy, will be much benefited by having some kind of shelter, as well as the more tender of the herbaceous plants. Half-hardy subjects which are being wintered in cold frames, such as pentstemons and calceolarias in variety should be kept safe by having a good lining of long litter placed round the frames, and the glass well covered whenever frost is likely to occur.

THE SHRUBBERIES.—Though I am an advocate of cleaning the whole of the leaves from the shrubbery beds and borders before the end of the old year, I am fully aware that it is absolutely necessary to preserve these in the best possible condition, to apply something in the way of feeding material. This should be applied at the earliest possible moment after this date. I know of nothing better than old hotbed manure for the purpose. Well-decayed garden refuse from a heap is also good for the purpose; this should be wheeled on during frosty weather, or when the surface is dry, and forked in when convenient, sometime before active growth commences.

PLANTING.—Though mid-winter is not an ideal time for transplanting shrubs and trees, it frequently happens, where a large amount of the work has to be done, that it has to be practised. Except in the case of hollies, and conifers generally, if great care is exercised there is no reason why this should not be safely accomplished. Too much care can hardly be taken in preserving a good ball and as many of the fibrous roots as possible; where of large size, suitable appliances must be brought into use. The holes should be large and well prepared, the roots carefully laid out, and any damaged ones cut back from the underside. Unless the soil is an ideal one, it will be necessary to spread a little well-prepared material over the roots to assist them to start away freely. The specimens should be made secure in some way to prevent the wind blowing them about. A thin mulching of half-decayed manure will also be advantageous to them. Any new beds or borders that are being made should now be well trenched, so that the soil is thoroughly exposed to the weather, which will render it suitable for receiving the plants early in April.—E. BECKETT, Aldenham House Gardens.

HARDY FRUITS.

GENERAL REMARKS.—As each season comes round it brings with it its own special work, and if one would succeed in the cultivation of hardy fruits, he must endeavour, as far as possible, to carry out the various items of work at the proper time. The last three months of the year are the most suitable for carrying out such work as root pruning, planting, and branch pruning, therefore it is advisable that the greater portion of this work should be performed by the end of the year, so as not to impede in any way the proper carrying out of the many items that require to be done during the first quarter of the year. This is not always practicable, hence reference is made to these operations.

PLANTING.—It is always advisable if the weather permits to plant new trees in their permanent positions as soon as possible after they are received from the nursery. They then at once commence to re-establish themselves in their new quarters by producing new roots. Trees laid in temporarily will also produce numerous roots, as in the former case, but these young roots, being very delicate, receive much damage when the trees are transferred to their proper positions. Hence the roots of trees which are treated in this fashion are not in such a good position for supplying moisture to the trees as in those trees that are planted on their arrival. It is therefore desirable to have everything in readiness, that they may be promptly planted in their new positions. On heavy soils let the trees be planted practically on the natural level of the ground, and then mound up the soil so as to well cover the roots, which should be spread out as evenly as possible, working some fine soil among them. Finish the operation by thoroughly making the soil firm over and about the roots. Place stakes to standard trees, fastening them securely, but a little loosely for the present, to allow them to sink slightly with the natural sinking of fresh-dug land.

PRUNING.—One of the chief objects in operating on trees growing as standards, pyramids, or bushes, and having ample room to develop, is to shorten the leading and main shoots just as much as will give the branches when carrying a good crop of fruit sufficient rigidity to prevent them breaking under the weight, and prevent their being swayed about easily by strong winds. Such winds, for example, as are experienced at the end of August and early part of September, when many of the varieties of the larger fruits, such as apples and pears, are approaching maturity, and are then more easily shaken off. Another object to be aimed at in pruning is to so shorten the leading growths as to ensure laterals and fruit spurs being produced along the whole length of the branches. If the latter are thinly and evenly distributed there will be nothing to prevent the free access of the sun and air to all parts of the trees. The lateral growths should be shortened to about three buds, or, in other words, to within an inch and a-half of their base. Trees in restricted areas require closer pruning.—GEORGE WOODGATE, Rolleston Hall Gardens.

STEWING PEARS.

The varieties of stewing pears are not numerous, nor is a wide range necessary, considering that those which are classed for the purpose are mostly of good quality, and are fine keepers. Of course, some of our dessert kinds, when cooked, are of the very best quality, but as their season is short they must be used almost at once.

In the variety Catillac we have one of the very best of croppers, standard trees bearing freely in most seasons, and the fruits, when cooked, become a very fine red colour. The pulp may be more gritty than that of some other kinds, yet it is excellent, and another good quality is that it keeps sound until the month of April. When grown as cordons the fruits come to a large size, and are fine for show purposes.

Verulam I have seen as a standard, bearing enormous crops. The fruits resemble greatly those of the old Brown Beurre in shape, and sometimes on the side next the sun the skin becomes a very dark brown colour. When stewed the flesh assumes a very pleasing colour, and is of good flavour. If the fruits are gathered at the right time they will keep sound until the middle of March.

Bellissime d'Hiver I used to grow as a bush, and it usually cropped very satisfactorily. The flesh is fine grained, white, and free from grit. In fact, at one time I thought it one of the best for baking purposes, as it was asked for in preference to Catillac and all others.

Uvedale's St. Germain is one of the largest pears we have. If given a good position on a wall it usually bears a fairly good crop of clean fruits. With me this variety is rather inclined to canker, but on some soils this may not be the case. The pulp, when cooked, is very pleasant, and not very gritty.

Beurre Clairgeau both bakes and stews well, although it is not classed as a cooking variety, but it is, in some gardens, more adapted for either stewing or baking than for dessert. A pear which when cooked is quite excellent is Jersey Gratioli, a variety which does not keep long after it is ripe, and which, with me, in Kent, bore very heavily. H. MARKHAM.

Wrotham Park Gardens.

CANARY GUANO,

"The Best in the World"

For GARDEN and GREENHOUSE.

Canary Guano ensures perfection in Flower, Fruit, and Foliage; there is nothing like it for producing luxuriant growth.

Thousands of Prizes are obtained by its use every year.

It is used in the Royal Gardens and by leading professional gardeners and principal trade growers throughout the kingdom.

Sold in Tins, **6d., 1/-,** and **2/6** each.
Bags: 14 lb., **3/6**; 28 lb., **6/-**; 56 lb., **11/-**; 1 cwt., **20/-** each.

Canary Guano may be obtained through any Seedsmen, or direct from the manufacturers—

A RARE OLD FLORIST'S FLOWER.

How is it that in the whole range of English floricultural literature we have no such thing as a book on the tulip. There are a few little pamphlets and cultural treatises extant, but a book in the proper sense of the word there is none. And this is all the more remarkable when we consider the high position that the tulip once occupied as a florist's flower, both at home and abroad. Many writers have discoursed upon its history and culture. Many, too, have told us of the marvels of the famous tulipomania that raged in Holland during the 17th century, and with which in a greater or less degree readers are already familiar. My present purpose, however, is not to deal with this oft-repeated theme, but rather to give a few literary notes concerning the flower as a popular favourite among growers who cherished it for its own sake, and for its beauty, rather than as an object of speculation.

There can be no doubt that the tulip made its first appearance in European gardens during the 16th century, and that for a time it shared with the carnation, the ranunculus, and the anemone, the esteem of the genuine lover of flowers. In fact, these four, with the auricula and the hyacinth, were practically the most widely grown and most highly prized florist's flowers during the 17th and 18th centuries. Some of them, but particularly the tulips, continued to be so well into the 19th century, and the efforts of the English florists finally resulted in the production of a type that, judged by the florists' standard of perfection, had never previously been attained. Groom, Goldham, Maddocks, Clarke, Greig, Sherwood, Davy, and others were well-known growers and raisers nearly a century ago, and their triumphs may be found chronicled in the columns of the gardening press of the period.

Some ten years ago Count Sohns-Laubach, Professor of Botany at Strasburg University, wrote an excellent treatise entitled "Die Geschichte der Tulpen in Mittel-und-Westeuropa." As a literary and historical account of the tulip it has probably no equal in modern times, for he covers the whole scope of tulip lore, beginning with Busbequins in 1554, who was the first to mention it, and appends to his treatise a comprehensive list of tulip literature in all languages and from all time, that was known to him.

A large proportion of the oldest books on this famous flower were, of course, written in Dutch, and this fact renders original research a matter of some difficulty to ordinary English writers. But the tulip was not long before it made its way into France, and there is much interesting historical and literary matter that can be gleaned about the flower from this source. To those readers who care to undertake the labour of original research, and we fear there are but few nowadays who have either the time or capacity for such work, some of our references may be useful, inasmuch as they are chiefly historical and cultural, whereas the Dutch literature largely relates to the mania and the speculation resulting therefrom. The high prices paid for tulip bulbs during the 17th century were those paid by the gamblers, not those by florists. Among the varieties that fetched high prices were the famous Semper Augustus, Viceroy, Admiral Siefkin, Admiral Von der Eyk, Brabanter, Gouda, Beste Anvaers, etc., and in reading of the enormous sums these flowers have fetched we have often wondered what they were like, and whether there still existed any representations of them in any of the Continental works on floriculture. Count Sohns-Laubach work excepted, we know of none, but in that work there is a coloured illustration of three of the most famous of these old-time tulips, viz., Viceroy, Gouda, and Semper Augustus, copied from an original drawing in the possession of Mr. Krelage, the eminent Dutch nurseryman, whose library contains many literary treasures relating to the tulip and other flowers.

Some of the early writers who mentioned the tulip were Gerard, Parkinson, Clusius, and Ferrari. Of course, many others have followed, both from a botanical and horticultural point of view. At one time the flower was simply divided into three sections, early, mid-season, and late, but the florists of various countries and of various times made their own sections and sometimes sub-sections. The French had their glacées, panachées, agates, marquetines, fantasques, jaspées, ranées, morillons, etc. The English in Maddock's day had five distinct sections, viz., the Primo Baguets, Baguet Rigauts, Incomparable Verports, Bybloemens, and Bizards, which fifty years later were reduced to four, the Bizarre, Bylomen, Rose, and Self, while the Dutch had six classes. At a very early stage in the tulip's existence as a florist's flower, the nomenclature began to assume a considerable importance, and the number of varieties was immense. The earliest independent French treatise we know of is "Le Floriste François," published in 1658, and this deals exclusively with the history and culture of the tulip, and contains an alphabetical list of the flowers then known. There are twenty-two pages, containing the names and descriptions of these old-time tulips.

Pierre Morin was one of two brothers who were eminent florists in Paris during the 17th century. His "Remarques Necessaires pour la Culture des Fleurs" ran through many editions, and in the one before me, dated 1670, there are several quaint little catalogues of his bound up at the end of the volume. The tulips form one by themselves, and their season of flowering, early, mid-season, or late, is duly noted. The names are mostly French, and as the tulip had not long been introduced into that country, it is evident that the French florists had been busy in the work of seedling raising.

Another quaint old French book that deals with the history and culture of the tulip is "Connoissance et Culture Parfaite des Belles Fleurs," published in 1696. In this there is no list, but we learn from the opening chapter that the tulip was the Queen of Flowers, that many had given up the culture of the anemone and carnation for the tulip, which had then been known in Paris only about 50 years.

The great French gardener De la Quintinye, published in 1690 his famous "Instructions pour les Jardins Fruitiers et Potagers," which ran through several editions, and had an enormous influence on French gardening. In my copy, dated 1700, there is a work at the end entitled "Nouvelle Instruction pour la Culture des Fleurs," bearing the same date, but which is generally agreed not to have been written by De la Quintinye. In this work we find an important chapter on the tulip, dealing with its classification as a florist's flower, its culture, and a long alphabetical list in double columns of over 400 varieties.

My space is rather limited, and I can only briefly refer to a few other important works in which the tulip finds a place. Among English authors John Rea, in his "Flora Sen de Florum Cultura" (1676), devotes several pages to the flower, with descriptive lists, divided into early, middle, and late kinds. Although the names are strongly suggestive of Dutch and French origin, yet there are a few that would appear by their names to be of English origin.

The English love of floriculture is in a large measure known to be the result of the immigration of Flemish and Huguenot refugees, who brought with them in their flight from persecution their fondness for what we know as florist's flowers. The city of Norwich was at one time peopled largely by these refugees, and has always been a flower-loving city. In and around Spitalfields the silk weavers, mostly descendants from Huguenots, were great cultivators of florist's flowers, even down to quite modern times, and we have often heard from an old inhabitant of the district of the intense interest which they took in their flowers, and in the tulip in particular.

Among the authors on the tulip, which we do not find mentioned in Count Sohns-Laubach's list, is Van Oosten, the author of "The Dutch Gardener," who includes in that work (second edition, 1711) an important treatise, evidently a translation from some French author. We quote from the English edition, but the work also appeared in Dutch and in German, and probably they, too, contained the same treatise. We get some indication of a decline in the absorbing interest in the culture of the tulip for the first time in John Carpenter's "The Retired Gardener" (1717), where, in the chapter on tulips, probably a modified translation from Louis Liger's "Jardinier Fleuriste," he says "never flower made people take more notice of it than this. The passion persons have had for it is surprising; and there has not wanted some in the last age, who have given above three hundred livers (livres) for a tulip root. But now that heat is much abated."

We find no allusion in Count Sohns-Laubach's list to the "Traitè des fleurs à oignons," by Nicolas van Kampen et fils, published at Haarlem in 1760. This work contains an independent treatise of twenty pages on the tulip, and its perusal will interest those who are concerned with the early history, classification, etc., of the flower.

An anonymous French author (since discovered to be Moët) published a bulky little volume in 1754, entitled "Traité de la culture des Renoncules, des Œillets, des Auricules et des Tulipes." This treatise is considered by a well-known French critic to be a mere plagiarism of "Le Floriste François," published nearly a century before, and certainly in the few minutes at my disposal for verifying the alphabetical list of varieties it would seem that there is good reason for the allegation.

One of the most scholarly and capable writers of French flower books was the Père d'Ardine. He wrote quite a series of excellent little books on the popular flowers of his day, and among them was "Traitè des Tulipes." There are two editions, practically identical. One was published at Avignon, in 1760, the other at the same place, five years later. This little book of 252 pages, with several plates, contains a list of authorities, ancient and contemporary, consulted by the author, a man of learning and a florist to boot, together with an explanation of the many technical terms employed by the growers of his day. The historical, literary, and cultural matter render it of paramount importance to every tulip enthusiast interested in the flower who desires knowledge in all matters concerning it.

IRIS GERMANICA.

Supply the most beautiful and effective yellow, rose, purple, and blue blooms during May, June, and July.

12 distinct varieties - - 5/-

50 in 12 varieties - - 18/-

MAJESTIC DELPHINIUMS.

One of the most telling subjects. Their strong flower spikes, 6 or more feet high, in every shade of blue, are most effective during June, July, and August.

12 distinct varieties - - - - 7/6

To that great army of enthusiasts whose leisure is limited.

EASY culture and extreme hardiness, allied with bloom-producing qualities of the highest degree of excellence in colour, shape and size distinguish this collection of five. Where such a desirable combination exists, gardening becomes a REAL recreation, not an unwelcome extension of the day's work; a minimum expenditure of time and labour is rewarded by a maximum of results.

Choose your own position for any one of the five. PLANT THE WHOLE OF THEM NOW in ordinary garden soil, and, without any heavy demand on your time or knowledge, next summer, and many summers to come, will see a living mosaic of glowing colours in your garden.

Coming from York Nurseries, the headquarters of hardy plant culture in this country, each plant is necessarily a picture of robust health, requiring only air, water, and a moderate amount of sunshine for development.

Send your order along to-day. Packing free for cash; carriage paid on lots of 10/- or over in value.

UNWIN'S SWEET PEAS

Are noted for their quality and fixity of type the world over.

AWARDED TWO GOLD MEDALS, N.S.P.S.

The number after each variety indicates the number of seeds per packet.

My Novelties for 1909.

ACK UNWIN.—A fine rich rose flake on white ground. Nicely waved. 20, **6d.**
ROSABELLE HOARE.—Soft rose flake on white ground and of the same type and growth as Jack Unwin. 20, **6d.**
GLADYS FRENCH.—A light blue Helen Pierce, sure to become popular. 10, **1s. 6d.** **ZEPHYR.—Sold out.**

1909 Novelties of other Raisers.

KING EDWARD SPENCER.—A deep rich carmine scarlet of glossy effect. Per pkt., 10 seeds, **6d.**
MRS. ROUTZAHN.—Deep cream ground, with decided rose edge, large flower, of perfect form. 10, **6d.**
RAMONA SPENCER.—Clear white, delicately lined blush pink. 10, **6d.**
ASTA OHN.—Lavender tinted mauve, beautifully waved. 10, **6d.**

Novelties of 1908.

CHRISSIE UNWIN.—A grand light scarlet shaded cerise. It has a bold and wavy standard, and has become very popular. 15, **6d.**
MISS E. F. DRAYSON.—This is of the same type as the above, but is deeper and richer in colour. 20, **6d.**
BOBBY K.—A beautiful variety. The colour is a soft apple-blossom blush, and the flower is of the largest, wavy Countess Spencer type. Truly a grand variety in every way. 15, **6d.**
ETTA DYKE.—A grand white of the true Countess Spencer type. It comes quite true, and is a grand flower for exhibition or decorative purposes. This is of my own raising, and I believe it is the finest stock in the country 10, **6d.**
ST. GEORGE.—A most brilliant orange salmon. A most popular variety. 8, **6d.**
EVELYN HEMUS.—Creamy yellow, edged pink. 10, **6d.**
CONSTANCE OLIVER.—A delicate soft pink suffused with cream on a cream ground. A grand variety. 7, **6d.**; 15, **1s.**
MARJORIE WILLIS.—Deep rose Spencer. 7, **6d.**; 15, **1s.**
SUTTON'S QUEEN.—A soft apricot pink. 15, **6d.**
ROSIE ADAMS.—A large rosy-mauve standard, with lighter violet wings of the Spencer type. 12, **6d.**
PARADISE RED FLAKE.—A deep red flake Spencer, on a white ground, a showy variety. 25, **6d.**
PRINCE OLAF.—A striped blue on a white ground. A pleasing variety. 25, **6d.**
HESTER.—After the style of marbled blue, slightly waved. 25, **3d.**
THE MARQUIS.—A rosy mauve, not yet fixed. 20, **6d.**

Best Standard Varieties.

WHITE.—Nora Unwin, the popular white, 25 ... ... **2d.**
ROSE.—John Ingman (True), a grand variety, 25 ... **4d.**
BLUSH.—Mrs. Sykes, soft pink Spencer, 15 ... ... **6d.**
PINK.—Countess Spencer (True), beautiful rich pink, 25 **4d.**
ORANGE.—Helen Lewis (True), best of its colour, 25 ... **6d.**
ORANGE.—Miss Willmott, an old favourite, 50 ... ... **2d.**
PRIMROSE.—Mrs. Collier, a good variety, 50 ... ... **3d.**
BLUE.—Zoë, best medium blue, 25 ... ... **2d.**
BLUE.—Lord Nelson, large deep blue, good, 25 ... ... **2d.**
CRIMSON.—King Edward VII., a great favourite, 50 ... **2d.**
SCARLET.—Queen Alexandra, the best sunproof scarlet, 50 **3d.**
MAUVE.—A. J. Cook, lovely violet mauve, 25 ... ... **2d.**
MAROON.—Black Knight, finest of its colour, 50 ... **2d.**
LAVENDER.—Frank Dolby, the best pale lavender, 25 **2d.**
PICOTEE.—Phenomenal, white, edged violet purple, 50 **3d.**
FANCIES.—Queen of Spain, lovely buff pink, 50 ... ... **3d.**
MARBLED.—Helen Pierce, a charming variety, 50 ... **2d.**

Special Gold Medal Collection.

The number of seeds in the following packets varies. The quantities are stated after each name.

CHRISSIE UNWIN, 16
FRANK DOLBY, 30
COUNTESS SPENCER (True), 30
NORA UNWIN, 30
LORD NELSON, 50
MRS. COLLIER, 50

ROSABELLE HOARE, 30
JOHN INGMAN (True), 20
HELEN PIERCE, 50
MISS WILLMOTT, 50
BLACK KNIGHT, 50
KING EDWARD VII., 50

Price 2/6 the Collection, 12 varieties;
Or half the above quantities, 12 varieties, 1/6.

SPECIAL NOTICE.—Unwin's own stocks of John Ingman, Helen Lewis, and Countess Spencer are the true wavy type and perfectly fixed. Before buying elsewhere, send for my catalogue and note the prices. None but the finest varieties offered, and all seeds of the best quality.

W. J. UNWIN, SWEET PEA SPECIALIST, HISTON, CAMBS.

Coming down to the close of the eighteenth century we must not forget to mention Maddock's "The Florist's Directory," the first edition of which appeared in 1792. At that time the most popular florist's flowers may be taken to be the hyacinth, tulip, ranunculus, auricula, carnation, pink, and polyanthus. The tulip was a favourite show flower, and continued to be so long into the nineteenth century. We have a curious old florist's book, entitled "An Account of the different Flower Shows held in Lancashire, Cheshire, Yorkshire, and other parts of the Kingdom in 1826, in which the tulip shows occupy a large portion. The details are not descriptive, but are given in the following order—Feathered Bizarres, Feathered Bybloemens, Feathered Roses. Flamed Bizarres, Flamed Bybloemens, Flamed Roses, and Selfs. Under these headings are given the names of the exhibitor, the order in which they showed, and the name of the winning variety. Here again it is apparent that we were still largely indebted to the French and Dutch florists for many of the famous tulips in the winning stands.

The prices paid for tulips during the tulipomania, of course, had nothing to do with their value from the florist's point of view. In later years large sums were occasionally paid for the stock of certain varieties, but in an ordinary way in Maddock's time, anyone could purchase bulbs of good varieties for a few shillings each. There were, of course, exceptions, and in Maddock's catalogue for 1792 we notice Habit de Parade £4 10s.; La Charmante, £4 4s.; La Reine de Toute, £5 5s.; Passe Thalestris, £5 5s.; Prince de Soubise, £4 4s.; Rose Desirè, £4 4s.; La Charbonnière, £5 5s.; Charlemont, £5 5s.; Hector, £4 4s.; Surpasse Catafalque, £6 6s.; Surpasse Pompe Funêbre £10 10s., and many others at lesser prices.

Certainly up to the middle of the nineteenth century tulip growing for show increased in popularity, and many fine examples of the old English tulip were raised. Floricultural literature of the period abounds in illustrations of these triumphs of the florist's art, and the records of the shows in the "Midland Florist," "The Florists' Register," and similar works prove the great interest that was taken in them at the time. In the first two or three decades of the nineteenth century the English show tulip had far surpassed the Continental ones, and in rapidly looking over the records of the period we have come across some fine illustrations in colour of many that occupied a foremost place, and of these Pandora, Fanny Kemble, Apelles, Queen Adelaide, Julia Grisi, Donizelli, Sultan, Salvator Rosa, Everard, Sir Robert Peel, Rose Camuse de Craiz, Elizabeth, Homer, Marcellus, Duchess of Kent, Majestueuse, Daveyana, Walworth, Earl of Liverpool, High Admiral, Polyphemus, were conspicuous examples. C. HARMAN PAYNE.

Home-made Raisins.—Mr. T. Coomber writes: The reference on page 942 of last year's volume to the raisins recently exhibited by Mr. Bennett-Poë recalls to my memory that the late Mr. James Esson, when gardener at Crimonmogate, Aberdeenshire, used to convert grapes into excellent raisins by placing the bunches in single layers, in shallow receptacles having ends and sides formed of wood, and tops and bottoms of perforated zinc. These "boxes" were placed over hot-water pipes, and occasionally turned over, until the process of raisin-making was completed. The raisins thus obtained were very highly valued for dessert.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

SCIENTIFIC COMMITTEE,
DECEMBER 22.

Present: Mr. E. A. Bowles, F.L.S. (in the chair); Messrs. A. W. Sutton, G. S. Saunders, J. T. Bennett-Poë, E. M. Holmes, H. J. Chapman, L. Crawshay, A. Worsley, F. J. Baker, J. Fraser, and F. J. Chittenden (secretary).

CALANTHE VARS.—Mr. H. J. Chapman showed two interesting hybrids of calanthe, one of a deep red, the other still deeper in colour. These are interesting on account of the spreading and intensification of the colour, as compared with the original species, C. vestita and C. rosea. The flower was deep red inside, but almost white externally.

MALFORMED CYCLAMEN.—Mr. Crawshay showed an interesting, though not very uncommon, malformation of the cyclamen where two flowers had been produced in the axils of two of the sepals of an otherwise quite normal flower. All the flowers on the plant, which was a seedling, were similarly malformed.

APPLES DECAYING.—Mr. Baker showed specimens of an apple with a wide open "eye," which was decaying from the core inwards. At the "eye" end of the fruit there was a deposit of some material which was thought to be possibly the remains of a spray fluid. It was taken by Mr. Holmes for further examination.

ALBINOS AMONG BRITISH WILD FLOWERS.—Mr. J. Fraser, F.L.S., showed specimens of an albino form of the ordinarily blue Gentiana campestris, remarking that he had found it occupying an area of several square yards at an elevation of about 1,000ft. in the Scottish highlands, while all the plants at a lower elevation were of the usual blue colour. The plant had evidently come true from seed, and this, he thought, was probably true of the majority of albinos when self-fertilised. There are numerous examples of albino varieties of British wild plants occurring naturally, and Mr. Fraser produced a list which, supplemented by other members, is given: Papaver Rheas, Matthiola incana, Viola odorata, V. hirta lactiflora, V. lutea amœna, Polygala vulgaris, P. serpyllacea, P. calcarea, Silene acaulis, Malva moschata, Geranium Robertianum, Ononis spinosa, Trifolium incarnatum, Rubus rusticanus, Rosa canina dumalis, R. c. surculosa, R. dumetorum, Epilobrum hirsutum, Scabiosa succisa, Centaurea nigra, Carduus nutans, Cnicus palustris, C. arvensis, Campanula rotundifolia, Calluna vulgaris, Erica tetralix, Erica cinerea, Centaurium umbellatum, Gentiana campestris, Verbascum nigrum, Bartsia odontites, Ballota nigra, Thymus Chamædrys, Galeopsis tetrahit, Ajuga reptans, Polygonum Bistorta, Orchis muscula, O. maculata, and Scilla non-scripta.

PLANTS IN BLOOM.—Mr. Bowles showed specimens of Felicia petiolaris gathered from the open in a Wimbledon garden, where the plant has flowered up to the present since the autumn. He also showed specimens of the following species of crocus which were flowering outdoors considerably before their normal period of bloom: Crocus Imperati (monophyllus) and a depauperate form of the same species, C. Selberi, and C. chrysanthus: C. Imperati was also shown from Wisley.

HEALING OF WOUNDS.—From Mr. Kingsmill came a portion of the trunk of an oak which had, many years ago, a piece of the stem cut off longitudinally. The wood had subsequently grown over the wound thus made, and completely healed it, so that no trace of the wound could be seen from the outside.

GREASE BANDS.—From Mr. J. Watkins, orchard foreman to Sir Edmund Loder, Maplehurst, Sussex, came a grease band from an apple tree with an enormous number of Winter Moths (Cheimatobia brumata and Hybernia aurantiana), both male and female, adhering to it. Mr. Watkins wrote that when he took the band off nearly 400 male and female moths were upon it, and that there were many bands on which 200 and upwards have been caught. The trees had never been banded before, but now some 10,000 had been done. The Mottled Umber Moth was the first to be caught, but later the Small Winter Moth in much greater abundance. The birds appear to take a great number of the moths from the bands and devour them, particularly the blue tits. Few moths were caught when the bands were first put on (in the first week in October). The larger proportion of females was caught from the middle to the end of November, and a few are still going up. Males were more abundant earlier. The Mottled Umber has been caught chiefly round the edges of the plantation, near the hedges and large oaks.

NEW PLANTS, ETC.

ACANTHUS MONTANUS.

An old, but rare species, from West Africa. It has a very distinct resemblance to the hardy species, but is itself a stove plant. The bracteate inflorescence is soft rose-purple in effect, but the flowers themselves are white, the bracts showing up very conspicuously. The leaves are deeply cut, spiny, and mottled in two shades of green. The plant, as shown, is a very attractive one. F.C.C., R.H.S., December 22. Messrs. James Veitch and Sons, Chelsea.

CALANTHE ANGELA.

A beautiful new calanthe derived from C. Burfordiensis and C. Chapmani. It is brighter than the latter, and differs in having a well-defined three-lobed lip. The latter is brilliant ruby-crimson, and the sepals and petals are a shade or so paler. F.C.C., R.H.S., December 22. Mr. H. J. Chapman, gardener to N. C. Cookson, Esq., Oakwood, Wylam-on-Tyne.

CYPRIPEDIUM ANTINOUS.

This handsome and large-flowered cypripedium is from C. J. Howes, crossed with C. Actæus. It has a broad and bold dorsal sepal that is white, with a green base and purple spots; the lip and petals are yellowish-green tinged with brown. F.C.C., R.H.S., December 22. Mr. H. G. Alexander, orchid grower to Lieut.-Colonel Holford, Westonbirt, Tetbury, Gloucester.

CALANTHE NORMAN.

This is another fine new calanthe, but it was overshadowed by the brilliant C. Angela. It has large flowers of rich rosy-crimson colour, the sepals being tipped with soft white. A.M., R.H.S., December 22. Mr. Norman C. Cookson.

ONCIDIUM BICALLOSUM, SANDER'S VAR.

A distinct and very fine form of an old species. It has a large yellow lip and brown sepals and petals, and is in every way a glorified form of the type. A.M., R.H.S., December 22. Messrs. Sander and Sons, St. Albans.

SARCOCOCCA RUSCIFOLIA.

This dwarf evergreen shrub is a recent introduction from China. It has shiny green ruscus-like foliage, is quite hardy, and promises to be very useful, as it will stand hard wear like a privet. The flowers are white, sweet-scented, and followed by blue berries. A.M., R.H.S., December 22. Messrs. James Veitch and Sons, Chelsea

APPLE ENCORE.

This useful apple has been previously described in our columns, as it gained an A.M. in December, 1906. F.C.C., R.H.S., December 22. Mr. C. Ross, The Gardens, Welford Park, Newbury.

WARE WIREWORMS!

Of all insect pests that ravage flower and kitchen gardens, the wireworm is the deadliest. The damage it does annually is appalling.

To exterminate the wireworm, the centipede, the leather jacket, the eel-worm and the millipede that ruin your garden, use

KILOGRUB

the surest and most effective pest-destroyer yet produced, and use it **now.**

"Kilogrub" is a chemical powder, which, well worked into the soil, gives out fumes which are fatal.

No insect pest can live on "Kilogrub" treated soil.

Only 2 or 3 ounces are necessary for a square yard.

Remember:—Kilogrub is a proved success—try it to-day.

Prices, cash with order carriage paid:—

7 lbs.	**2s. 0d.**	½ cwt.	**7s. 0d.**
¼ cwt.	**5s. 0d.**	1 cwt.	**11s. 6d.**

SPECIAL NOVELTY OFFER.

1 full-sized packet of each of the 10 Grand Novelties post free for 9/6.

1 full-sized packet of each of the Novelties, and also the Villa (C) Collection, post free for 11/0.

ANSWERS TO CORRESPONDENTS.

PRUNING HYDRANGEA PANICULATA GRANDIFLORA.—P. M. S., Keighley: This hardy flowering shrub delights in fairly heavy soil. When grown as a lawn group the shoots produced in the previous season should be cut hard back to within a few inches of the soil, as then new strong growths will start from the base and flower finely.

NEW NEPHROLEPIS.—F. F. S., Manchester: The new varieties of Nephrolepis exaltata arrive so fast that it is a difficult matter to keep pace with them; indeed, at the present rate of increase there will soon be sufficient to enable anyone so minded to start the cult of the nephrolepis in much the same way that some take up varieties of Odontoglossum crispum or Cypripedium insigne. A few of the varieties that occur to us are N. todeaoides, N. superba, N. elegantissima, N. Scotti, N. Bostoniensis, N. Whitmanni, and N. Scholzeli.

HARDY ANNUALS FOR A NEW GARDEN.—T. C. M., Coulsden: The following are among the very best of hardy annuals. Of most kinds there are numerous varieties, but a good seed catalogue from any of the firms advertising in our columns will help you in the selection of varieties. The kinds are: Calandrinia, calendula, candytuft, clarkia, coreopsis, cornflowers, gilia, godetia, larkspur, linum, lupin, mignonette, phacelia, and poppy. Stocks, asters, tropæolums, and annual chrysanthemums, all half-hardy, could, without much difficulty, be raised in a frame or cool house, and they would amply repay the trouble taken with them. French and African marigolds and zinnias come under the same category. Tropæolums may be sown out of doors in spring, or in an unheated frame in March, to be planted out when fear of frost has passed.

RAISING CELERY AND LEEKS.—A. L. C., Durham: Early celery may be sown about the third week in February, and the main crop about the first week in March. One sowing of leeks will usually suffice, and this should be made at the end of January. In raising both celery and leeks, prepare shallow boxes by placing a thin layer of crocks in the bottom; then cover with decayed leaves or other loose material, and fill to within about half an inch of the upper edge of the sides with rather fine soil, which should be pressed moderately firm. Sow the seeds thinly, give the surface a liberal sprinkling of water, and place in a frame or house in which a temperature of between 60 and 65 degrees is maintained. As soon as the young plants are making their appearance above the surface place the boxes in a light position near the glass, and maintain the soil in a moderately moist condition. Leaving the seedlings in the seed boxes until the plants are being injured by overcrowding must be avoided, and the proper course is to transplant the celery when the plants have made their first rough leaf, and the leeks when they are two or three inches high. They are best put into shallow boxes, and these should, as in the case of those in which the seed was sown, have crocks and loose material put in the bottom. Instead of fine soil the boxes should be filled with a rich compost. The plants should be put three inches apart in the boxes, and be kept close and warm until they have recovered from the check received in planting. They must then be gradually hardened by an increase in the ventilation, and be then removed to an unheated frame, where they should enjoy a free circulation of air and uninterrupted light, excepting, perhaps, in brilliant sunlight, when a very light shade may be used. All the changes must be gradual, and close attention be paid to the water supply, which should be moderately liberal. Leeks should be planted direct from the boxes into their trenches, but the celery will require to be transplanted to a bed of rich soil made up in an unheated frame or in a sheltered position out of doors, where protection from brilliant sunlight by day and from frosts and cold winds at night can be readily afforded.

COMMON POISONOUS PLANTS.—N. G. G., Saxmundham: A few of the commoner poisonous plants met with in lanes and gardens are: Foxglove, leaves; monkshood, leaves and roots; deadly nightshade, berries; wild arum, leaves, etc.; water hemlock, leaves; water parsnip, roots and leaves; hemlock, stem and leaves; laurel, leaves and berries; yew, leaves and seeds; and laburnum, seeds.

NITRO-BACTERINE.—F. H. W., York: The experiments carried out by Mr. F. G. Chittenden, at the R.H.S. gardens, show that for edible peas nitro-bacterine serves no useful purpose at all. Every care was taken to conduct the trials in a manner that would admit of no possibility of error, and the results, as published in the recent issue of the society's "Journal," are distinctly unfavourable to the inoculation of seeds or soil with nitro-bacterine.

BLANCHING LEEKS.—A. L. C., Durham: The great mistake you have made is that of imagining the leeks can be properly blanched at any period, provided their stems are covered. Earthing up should commence about a month after planting, and the work should be continued every ten days or so until there is a length of twelve or more inches of stem beneath the soil, and the plant has ceased to extend. Clever leek growers use a stiff cardboard collar, placing this around the leek and drawing it up as the work of blanching proceeds.

NAMES OF FRUITS.

S. N., Lynn.—1, Newton Wonder; 2, Fearn's Pippin.

H. L. C., Warminster.—1, Beurre Diel; 2, Lane's Prince Albert; 3, Mère de Ménage.

R. D. G., Somerset.—1, Kerry Pippin; 2, Dumelow's Seedling; 3, Ribston Pippin; 4, not recognised.

F. W., Oxford.—The two small specimens were so small and scabby that it was quite impossible to identify them.

J. B., Poynton.—1, Probably a poorly-coloured Worcester Pearmain; 2, not recognised; 3, evidently a local seedling.

NAMES OF PLANTS.

S. W. P., Holmwood.—Probably Pyrola rotundifolia, but, as you observe, the specimens are not very good ones.

D. C., Retford.—1, Viburnum Tinus; 2, Callicarpa purpurea; 3, Echeveria secunda glauca; 4, Gaultheria procumbens.

J. A., Bournemouth.—1, An olearia, probably O. stellularia; 2, Thuia dolobrata variegata; 3, Thuia dolobrata; 4, not recognised, probably a pittosporum; please send when in flower.

FORTHCOMING ENGAGEMENTS.

MONDAY, January 11.—United Horticultural Benefit and Provident Society; committee meeting.

TUESDAY, January 12. — Royal Horticultural Society; committees meet at 12 o'clock; general meeting at 3 o'clock; Scientific Committee at 4 o'clock.

SATURDAY, January 23.—Annual dinner of the French Horticultural Society of London, at the Café Royal, at 6.30 p.m.; Sir Albert K. Rollit will preside.

Horticultural Societies. — The "Gardening Year Book" for 1909, just issued, contains a full list of the horticultural and botanical societies of the United Kingdom, with the name and address of each secretary, and, so far as could be ascertained at the time of going to press, the dates of the exhibitions for the present year. An additional feature is a directory of the public parks and gardens of the United Kingdom, giving area, name of superintendent, etc. The body of the work is devoted to sound information on the general work in the garden and greenhouse for the whole year, a description of the new plants, flowers, fruit, and orchids, many special articles on sweet peas, bulbs, dahlias, chrysanthemums, and other subjects, and selections of the finest of both hardy and tender ornamental plants, and of fruits and vegetables. The price is 1s., or by post 1s. 3d., from the GARDENERS' MAGAZINE office, 148 and 149, Aldersgate Street, London, E.C.

25 PER CENT. CHEAPER THAN OTHER BRANDS.

SUTTON'S GARDEN PEAS.

During the long History of our Firm the new strains of Vegetables introduced by us have increased the quantity, improved the quality, and extended the duration of all kinds of garden produce; and the results of unremitting labour have never been more apparent than in the New and Improved Varieties we now offer.

In Garden Peas especially, we have by cross-breeding and selection secured such marvellous developments that, under suitable cultivation, Marrowfat Peas of exquisite flavour are now available as table delicacies from May to November, and the handsome pods win Premier Honours on the Exhibition stage.

SUTTON'S PIONEER PEA, per pint, **2s.;** per quart, **3s. 6d.**

SUTTON'S DELICIOUS PEAS SEVEN MONTHS IN THE YEAR.

Special Collections of some of our best varieties, to produce (under suitable conditions of culture) the finest Peas for table or exhibition from May to November.

TO-DAY! AND FOR YEARS AND YEARS PAST the XL ALL Specialities are and have been the best on the market. Where is the Gardener who does not pin his faith to one or the other of these celebrated Insecticides or Fertilisers? XL ALL FERTILISER has pleased all who have used it this season. The Sales of XL ALL FUMIGATOR prove that it is more popular than ever. XL ALL LIQUID NICOTINE INSECTICIDE is always spoken of by gardeners and growers as the most deadly to Mealy Bug, Thrip, etc. XL ALL WINTER WASH for dormant Trees acts like magic, clearing the Trees and Bushes of all Insects' Eggs, Moss, and Fungoid Growths. XL ALL LAWN SAND, a weed eradicator and fertiliser for weedy and poor lawns. XL ALL WEED KILLER used once a year "No weeds can live." Please ask your Nurseryman, Seedsman, or Florist for a copy of my small pink list, giving particulars of these and many other XL ALL Preparations, which can be obtained from the Horticultural Trade throughout the World. G. H. RICHARDS, Manufacturer and Patentee, 234 Borough High Street, London, S.E.

Burpee's
The Leading American Seed Catalog for 1909!

The "SILENT SALESMAN" of the World's Largest Mail-Order Seed Trade is a **New BOOK of 174 pages.** It describes Rare Novelties which cannot be had elsewhere, and tells the *plain truth* about the Best Seeds that can be grown—as proved at our famous FORDHOOK FARMS—the largest and most complete Trial Grounds in America. Handsomely bound in covers lithographed in nine colours, it shows, with the beautiful coloured plates (also in nine colours), Seven Choice Novelties in Vegetables, Three Superb "Spencer" Sweet Peas, and the most beautiful new Giant-flowered Pansies—all accurately painted from nature. With hundreds of illustrations from photographs and carefully-written descriptions, it is A SAFE GUIDE to success in the garden, and should be consulted by everyone who plants either for pleasure or profit. While too costly a book to send unsolicited (except to our regular customers), we are pleased to mail it **FREE to every one** who *has a garden*, and can appreciate QUALITY IN SEEDS. Shall we mail YOU a copy? If so, kindly *name this paper* and **write TO-DAY!**

THE GARDENERS' MAGAZINE.

NOTES OF THE WEEK.

Fruit Tree Planting.

There is probably no point in the cultivation of hardy fruits in which there is such a remarkable consensus of opinion as with regard to the manner in which fruit trees should be planted. The majority of, if not all, growers with experience are in agreement with the advice so generally given, that in planting fruit trees the holes taken out should be large enough for the roots to be evenly spread out without twisting or bending, that soil should be carefully worked among the roots, and that when these have been sufficiently covered to prevent their being injured, the soil should be firmly trodden in the process of filling in the holes. Hence the results obtained in the experiments in tree planting that are being conducted on the Woburn Experimental Fruit Farm, will come somewhat as a shock to a very large proportion of those who are engaged in fruit culture. These results would appear to show that the careful manipulation of the roots on which for so long a period much stress has been laid, is not only unnecessary, but that a different practice may with advantage be adopted. These experiments and the results obtained are of special interest from the fact that they had their origin in the desire to show the advantage of carrying out with care the generally accepted orthodox practice. The Duke of Bedford and Mr. Spencer Pickering, the authors of the report, state that "one out of sixty plots of apple trees which were subjected to various different treatments for experimental purposes, was planted in violation of the accepted canons of 'good practice,' in order to obtain some measure of the importance of careful planting, and to afford an object-lesson to visitors of the evils of bad planting." The trees, however, did better than their properly planted neighbours, and to avoid the possibility of error through local influence, the experiment was repeated on a more extended scale with other trees. The results, however, were more decisive than ever in favour of unorthodox planting, and these were confirmed by a third, fourth, and fifth repetition in subsequent years. Experiments have, in addition to those at Ridgmont, been conducted at Harpenden and in fifteen other localities, and altogether 2,000 trees have been utilised, and evidence of the most trustworthy character obtained. The authors state that in the first few experiments on orthodox planting the roots of the trees were not trimmed, but huddled into holes, too small to receive the roots properly, and many of them, instead of being spread out, were pointing downwards or bent. Further that the earth was not shaken in amongst the roots but was thrown on the top, and the whole stamped violently. That trees should be planted firmly in the soil is well known and generally acted upon, but the ramming process adopted in these experiments was, we are told, very different from what would be termed firm planting. "A few forkfuls of earth were removed so as to make a shallow hole; into this the tree was put, with the roots just as they happened to come, the earth was shovelled over them, and rammed with a heavy rammer till the whole was thoroughly puddled, and shook like a jelly at each stroke." The consolidation of the soil round the roots is such that the ground generally remains quite hard during the next twelve months, and even during the second and third years it is possible to recognise the trees that have been rammed by merely pressing the ground with the foot. In all cases where trees have been planted with ramming, the same number of trees, of the same variety, of the same age, and, as nearly as possible, of the same weight, have been planted side by side with them in the orthodox manner with due care. The planting was done at various times throughout the dormant season, and "in some cases the soil was in such a soppy condition that ordinary planting was out of the question." As pointed out in the report, soil, after being puddled in the manner described, is in a most unsuitable condition for vegetation, and if the whole field, or even any large area round the trees were thus treated, the results would be disastrous. But the ramming "is only done over the roots themselves, and before the end of the first season the new roots formed are found to have penetrated beyond the ball of consolidated earth into the loose ground beyond." The several tables given, showing the effect of unorthodox planting on apple trees, are of much interest, and should be carefully examined by those who are interested in this important matter. For our purpose it will suffice to say that of the 70 sets the first year, 41 were in favour of ramming, 19 sets gave no results, and 10 sets were against ramming. With regard to the second year's growth 54 sets were available, and of these 39 were in favour of ramming, nine gave

MR. J. B. STEVENSON,
Superintendent of the Bournemouth Public Parks and Gardens.

no results, and six were against ramming. The effect on root formation, as so well shown in the photographic reproductions, was decidedly in favour of ramming, there being an enormous development of root fibres, as compared with the root systems of trees planted in accordance with orthodox practice. With reference to the effect of ramming on fruit production, none of the plots of apple trees have been left long enough to afford definite evidence, and trees were not allowed to fruit the first and second year. With the bush fruits the crops yielded during the second season after planting, by gooseberries, raspberries, and black currants were alike notably larger, the average excess of the three kinds being 76 per cent. The explanation of the advantages of ramming the soil is in the authors' opinion, "simply that the more intimate contact of the soil with the roots favours the development of a large number of new rootlets from them," and thereby increases the capacity of the root system in providing the trees with the needful supplies of nutriment.

Mr. J. B. Stevenson has, during the past twenty-one years, accomplished so much in developing the horticultural aspects of Bournemouth, and thereby contributed materially to the enjoyment of the many thousands who annually resort to the town for pleasure or the improvement of their health, that we have much satisfaction in presenting our readers with his portrait. A Scotchman by birth, Mr. Stevenson showed early in life a taste for gardening, and the first step that was taken in his training in practical horticulture was his being apprenticed to a nurseryman at Hawick, N.B. Subsequent to his apprenticeship, Mr. Stevenson served in several important gardening establishments in the North of England, and possessing ability of an exceptionally high order, he attained to the position of head gardener at a comparatively early age, and after having reached this position his progress was rapid. Immediately preceding his appointment to the important position he now holds, Mr. Stevenson was head gardener at Partrick House, Swanage, the residence of G. Burt, Esq., and while there he laid out the greater part of the Dirlstone estate for Mr. Burt. In the year 1887 Mr. Stevenson was appointed superintendent of the parks and gardens belonging to the Corporation of Bournemouth, and during the twenty-one years the open spaces under his charge have been greatly increased and much improved. The latest additions have been the King's and Queen's Parks at Boscombe. We need not enumerate the parks and gardens under Mr. Stevenson's direction; they are many, they are all more or less beautiful, and they bear conclusive evidence of skill and judgment in their management. The judgment shown is made abundantly evident by the skill that has been shown in the preservation of the natural features of the several parks and gardens, and in the concealment of the art to which they owe so much of their charm. Annually displays of spring and summer flowering plants are provided in the gardens, and these invariably afford object-lessons of much value in the utilisation in the respective seasons of the subjects most suitable for beautifying the flower garden. While both displays are of quite exceptional merit, the beautiful arrangements of flowers belonging to the spring are, perhaps, the most noteworthy. They certainly contribute in no small degree to the popularity of the gardens, and the high estimation in which Mr. Stevenson is held by those who are well acquainted with his work.

Victoria Medal of Honour.—The vacancies in the roll of the Victoria Medal of Honour in Horticulture caused by the death of Mr. George Nicholson and Mr. Martin Smith, have been filled by the President and Council of the Royal Horticultural Society conferring medals upon Sir Jeremiah Colman, Bart., and Mr. Charles Ross. We have during the past year presented our readers with portraits of these distinguished horticulturists, and given short sketches of the services they have rendered to horticulture.

Forcing by Means of a Hot-water Bath.—Over thirty years ago the late Mr. Robert Owbridge, of Church Walk Nurseries, Stoke Newington, was a frequent contributor to these pages, and he showed how easy it was to force shoots of flowering shrubs into bloom by means of a hot-water bath. He had occasion, owing to building operations, to cut down several large magnolias (M. conspicua) early in the year, and he placed the cut branches in a tank of warm water, where they quickly swelled up their flower buds and expanded their beautiful flowers; these latter were sent to market and secured excellent prices. Quite recently this method of forcing has been brought forward as something quite new, but the only new part about it is that efforts are being made to discover the best time to cut branches for the purpose and the best temperature at which to keep the water. We learn from "Nature" that Dr. H. Molisch, of Vienna, has recently described some experiments upon forcing the resting shoots of woody plants by soaking them in warm water. Twigs of the hazel, bearing male catkins, placed for twelve hours in a bath registering about 30 degs. Cent., in Mid-November, and then removed to a warm house, were hastened into flower in eight days. Flowers of forsythia similarly treated developed in a fortnight. Lilac, dog-wood, horse-chestnut, and other shrubs or trees were also responsive to treatment. The stimulus is only effectual at a certain period, and appears to be distinctly localised. Staminate buds of hazel could be forced in November, but twigs bearing pistillate flowers could not be stimulated until December.

Winter Flowers at Abbotsbury.—As illustrating the mildness of the weather previous to Christmas Day, Mary Countess of Ilchester writes from Abbotsbury Castle, Dorchester: "I am venturing to send you the subjoined list of 120 flowering shrubs and plants that were blooming in the open air in my garden here on December 20, 1908." The list includes abelias, acacias, choisyas, coronillas, cytisus, daphnes, hydrangeas, jasmines, including Jasminum primulinum, lapagerias, narcissi, rhododendrons, spiræas, salvias, and verbenas. It should be added that the gardens of Abbotsbury Castle occupy one of the most favoured positions on the south coast.

Flowers of Switzerland.—At the conversazione of the Horticultural Club, to be held after the monthly house dinner, on January 12, at 6 p.m., at the Hotel Windsor, Victoria Street, S.W., the Rev. Canon Horsley will lecture upon "Flowers of Switzerland," and his lecture will be illustrated by unpublished slides of the people and scenery of the Bernese Oberland.

New Park for Lurgan.—The town of Lurgan, co. Armagh, is adding to its amenities by the creation of a new public park, with an area of 70 acres. Plans for laying out the ground were invited, and the first premium in the competition has been awarded to Messrs. J. Cheal and Sons, of Crawley.

Royal Gardeners' Orphan Fund.—The annual festival dinner of this charity will be held at the Hotel Cecil on May 6. His Grace the Duke of Rutland will preside.

Mr. T. H. Slade, who has during the past fourteen years occupied the position of head gardener at Poltimore Park, Exeter, is, through changes consequent on the death of the late Lord Poltimore, relinquishing his charge. So able an administrator and skilful a cultivator should not be long before obtaining other opportunities for the exercise of his abilities.

Florists' Workshops.—We are informed by the Home Office that in pursuance of section 59 of the Factory and Workshop Act, 1901, the order made on October 13, 1908, granting a special exception to florists' workshops under section 46 of the said Act and so much of the order made on October 13, 1908, granting a special exception under section 45 of the said Act, as relates to florists' workshops, has been rescinded.

The Royal Horticultural Society of Ireland has suffered a loss of about £100 on the work of the year 1908, but, fortunately, it has a reserve fund to fall back upon. The prospects for 1909 are better. There is an increase of sixty-two members, and arrangements have been made whereby the spring show will be held at Ballsbridge in conjunction with the Royal Dublin Society, the latter body having granted the use of the Arts Industries' Hall, and, in addition, promised a donation of £50 towards the show expenses. There will be a rose show in July and a fruit show in the autumn.

The Pink Anemones, so largely imported from France at Christmas and the New Year, have been not nearly so plentiful this season as usual, and enquiry elicits the fact that over large areas of the southern flower-growing districts these anemones are deteriorating rapidly, and that a kind of canker has attacked the fleshy roots. It appears that unless careful selection, raising clean stocks from seeds, or change of stock from cooler districts, are taken in hand promptly, the long-lasting flowers of the pink anemone may soon cease to be marketed in quantity.

The Darwin Commemoration Festival, to take place at Cambridge on June 22-24, 1909, promises to be a most interesting function. A large number of invitations have been sent out to British and foreign universities, colleges, academies, and learned societies, and already two hundred delegates, from North and South America, the countries of Europe, Japan, and the Colonies have signified their intention to be present. It is hoped that Lord Rayleigh will hold a reception on June 22; addresses will be presented on June 23 in the Senate House, and in the afternoon there will be a garden party in the grounds of Christ's College (Darwin's College), to be followed by a banquet in the evening. On Thursday, June 24, Sir Archibald Giekie, president of the Royal Society, will deliver the Rede lecture.

SWAYLANDS HOUSE, TUNBRIDGE WELLS.

GARDENS ROUND TUNBRIDGE WELLS—II.

Penshurst Place.

This stately old mansion, the residence of Lord de l'Isle, is one of the most ancient of the great seats in the neighbourhood of Tunbridge Wells, from which it is seven miles distant, and has long been one of the favourite show places in the district, and highly appreciated is the generosity of the noble owner in opening the house and grounds to the public on certain days of the week. With a history extending over seven or eight centuries Penshurst is rich in tradition, and its fine hall, built by Sir John de Pulteney about the middle of the thirteenth century, and its collection of family portraits by Vandyck, Holbein, De Heere, Gainsborough, and other artists of the highest eminence, render a visit of special interest to all who take an interest in past events and in men who have distinguished themselves, and thereby helped to make the history of their country. In the somewhat quaint and admirably kept gardens those interested in horticulture find much to give them pleasure, and it may be hoped, of profit also, for they are well able to afford object lessons of much value. It is a charming drive direct from Tunbridge Wells, as the country is richly diversified, but Penshurst is the most readily reached by taking the railway to the village of Penshurst, which is two miles distant.

It is generally conceded that the finest view of the old mansion is obtained from the north or Leigh end of the long avenue, which forms so noteworthy a feature. The park is extensive, and has many attractions, and one might well spend several hours among the trees that have in some way or other become famous. The park does not appear to have very favourably impressed Walpole, for after one of his visits he wrote, "The park is forlorn. Instead of Sacchaissa's cipher carved on the beeches I should sooner have expected to have found the milkwoman's score." But Walpole, like some lesser lights, was by no means free from prejudice, and from what we know of him there is no doubt that the thoroughly English character of Sir Philip Sidney, as revealed in his "Arcadia," did not appeal to him. Southey held a very different opinion, for he writes—

"Tread
As with a pilgrim's reverential thoughts
The groves of Penshurst, Sidney here was born,
Sidney, than whom no greater, braver man
His own delightful genius ever feign'd,
Illustrating the groves of Arcady
With courteous courage, and with loyal love."

Whether Sir Phillip Sidney wrote the "Arcadia" at Penshurst is matter for conjecture, but there can be no question that the district afforded the material for many of the descriptions therein. Not a few passages might be cited in proof, but the description of Laconia must suffice, and with reference to it it may be said that it conveys a very good idea of the distinguishing characteristics of the environs of Penshurst at the present day.

"There were hills which garnished their proud heights with stately trees; humble vallies, whose base estate seemed comforted with the refreshing of silver rivers; medowes enamelled with all sorts of eie-pleasing flowers, thickets which being lined with most pleasant shade, were witnessed so too. by the cheerfull disposition of many well-tuned birds; each pasture stored with sheep feeding with sober security, while the pretty lambs, with bleating oratory, craved the damme's comfort; here a shepheard's boy piping, as though hee should never be old; there a yong shepheardess, knitting and withal singing, and it seemed that her voyce comforted her hands to worke, and her hands kept time to her voice music. As for the houses of the country (for many houses come under their eye) they were all scattered, no two being one by the other, and yet not so farre off that it barred mutual succour; a shew, as it were of an accompaniable solitairnesse and of a civil wildnesse."

Passing from the mansion and park, with their many interesting historical and literary associations, to the gardens, one finds a great diversity of charms, and that which perhaps appeals the most strongly to the mind is the care that has been shown in shaping and maintaining the pleasaunce in a form that is in keeping with its environment. Under the shadow, figuratively speaking, of the walls of the ancient pile, is an old English flower garden, with its "knottes" enclosed in broad edgings of box, and filled with plants quiet in colouring and otherwise adapted to their surroundings. This garden, of which an illustration is given, was formed by Mr. Frederick Bridger, who, it may be of interest to know, was born at Penshurst Place, and has had charge of the gardens since 1868, when he succeeded his father, who had been head gardener forty-eight years. In another part of the grounds not far distant is a large and admirably grown collection of hardy plants. This hardy plant garden has been divided into a series of alleys by yew hedges about six feet high. Each alley has two broad borders, intersected by a grass walk of considerable breadth, and some have in each border a row of standard apple trees, as in the case of the one illustrated. The alleys with apple trees are the most picturesque, but it need not be said that the plants attain to the highest degree of perfection in those without them, and, in consequence, most, if not all, the choicer kinds are found therein. Full provisions have been made for the cultivation of the newer water lilies, and sites have been found for the basins where their newness, if the expression is admissible, do not contrast with the many evidences of antiquity.

ROCK AND WATER GARDEN, SWAYLANDS HOUSE.

There are other departments which the practical man would like to explore, and if I refrain from expressing an opinion of the skill that is everywhere evident it is because I feel that praise would be superfluous. I accordingly bring these brief notes to a close, and in doing so I am reminded, as when returning from Penshurst Place, of Ben Jonson's lines relating thereto:

> "Thou art not, Penshurst, built to envious show
> Of touch or marble; nor canst boast a row
> Of polish'd pillars or a roof of gold:
> Thou hast no lantern, whereof tales are told:
> Or stair, or courts; but stand'st an ancient pile,
> And (these grudged at) art reverenced the while.
> Thou joy'st in better marks, of soil, of air,
> Of wood, of water; therein thou art fair.
> Thou hast thy walks for health, as well as sport;
> Thy mount to which the Dryads do resort,
> When Pan and Bacchus their high feasts have made
> Beneath the broad beech and the chestnut shade."

Broom Hill.

This estate, the property of Sir David Salomons, the eminent electrician, occupies a prominent position in a fine open stretch of country between two and three miles beyond Southborough, which has now become a large and important suburb of Tunbridge Wells. Here we find rolling meadow and diversified woodland combining to make a series of pictures so charming in conception and magnificent in proportions as to produce a powerful impression upon those who are happy in the possession of an artistic temperament.

The mansion is a spacious structure of handsome elevation in the Italian style of architecture, and, for the most part, the walls are clothed with Irish ivy; it has also an air of space and comfort that can hardly fail to strongly appeal to those who care but little for houses in which light, and air, and space are sacrificed to ornate design. The gardens and pleasure grounds have an air of quietness which but few visitors can fail to appreciate, for Sir David Salomons regards his garden as a place wherein rest and refreshment of mind may be obtained, and he has also a strong affection for trees and shrubs that are indigenous to this country, or have so long had their home within its boundaries that they are now commonly regarded as such. Standing upon the broad terrace on the south side of the mansion, one is able to enjoy a prospect not less remarkable for its extent than for its exquisite beauty. On a lower slope, in the immediate foreground, the eye ranges over a series of flower beds tastefully filled with plants that give brightness to the scene without being strongly coloured, and is carried over bold masses of choice rhododendrons that, in their season, give a wealth of flowers, specimen trees, belts of shrubs, arrangements of hardy plants, and other subjects, all of which contribute their share to the attractions of the grounds. Included in the scheme of planting are a number of trees that are still regarded as exotics, and among them are some fine conifers, especially noteworthy for their development being the examples of Cedrus Deodara. The ground slopes sharply away from the house in all directions, and along the western side is a broad belt of trees, with a rivulet of water which has been so dealt with as to have been converted into a lake of considerable dimensions at the south-west corner of the grounds, where it forms a distinct and beautiful feature, with its bold background of aspens, willows, and other suitable trees, and groups of rhododendrons on the other side.

Another feature of interest is the fine laurel hedge which skirts the carriage drive on the east side of the mansion, and forms an excellent screen, and effectually shuts out from view the kitchen garden and other of the useful departments. This hedge is between fifteen and sixteen feet high, perfect in keeping, and its appearance suggests that the garden shears are not allowed to touch it when pruning is in progress. Fruit culture, and the production of flowers for decorations in a cut state form an important part of the matters to which Mr. J. Roberts, the able head gardener, has to give his attention, and in dealing with these, as with other points in the management of the gardens under him, affords abundant evidence of his judgment and skill. In the vineries, the vines, most of which were lifted and replanted a few years since, were carrying excellent crops. Peach and nectarine trees, in the structures devoted to these luscious fruits, were bearing abundantly, and the fruit was of high quality. The crops of cucumbers, melons, and tomatoes, which are grown on a large scale, were not less satisfactory. Under glass we noticed immense numbers of carnations, and it may be added that chrysanthemum culture is carried on extensively. Very interesting in the kitchen garden are the avenues of bush apple trees, for they are models of what such trees should be. They are tall and shapely, but the point of special importance is the fact that the leading branches are sufficiently far apart to admit of the production of fruit-bearing spurs throughout their length.

Swaylands House.

Within four or five miles north-west of Tunbridge Wells Swaylands House, the seat of G. J. Drummond, Esq., is reached, and whether the journey be made on foot or by one of the several means of locomotion now available, the visitors will not have long passed the garden gates before receiving an assurance of an ample recompense. There is much charming country between "the Wells" and "Swaylands," and if the opportunities for studying the characteristics of the scenery have been taken advantage of, the visitor will, on arrival at his destination, be in the best possible frame of mind for fully enjoying the charms in which these fine gardens are so rich. Whether interested in roses, rock gardening, or hardy plants, he will find abundant entertainment.

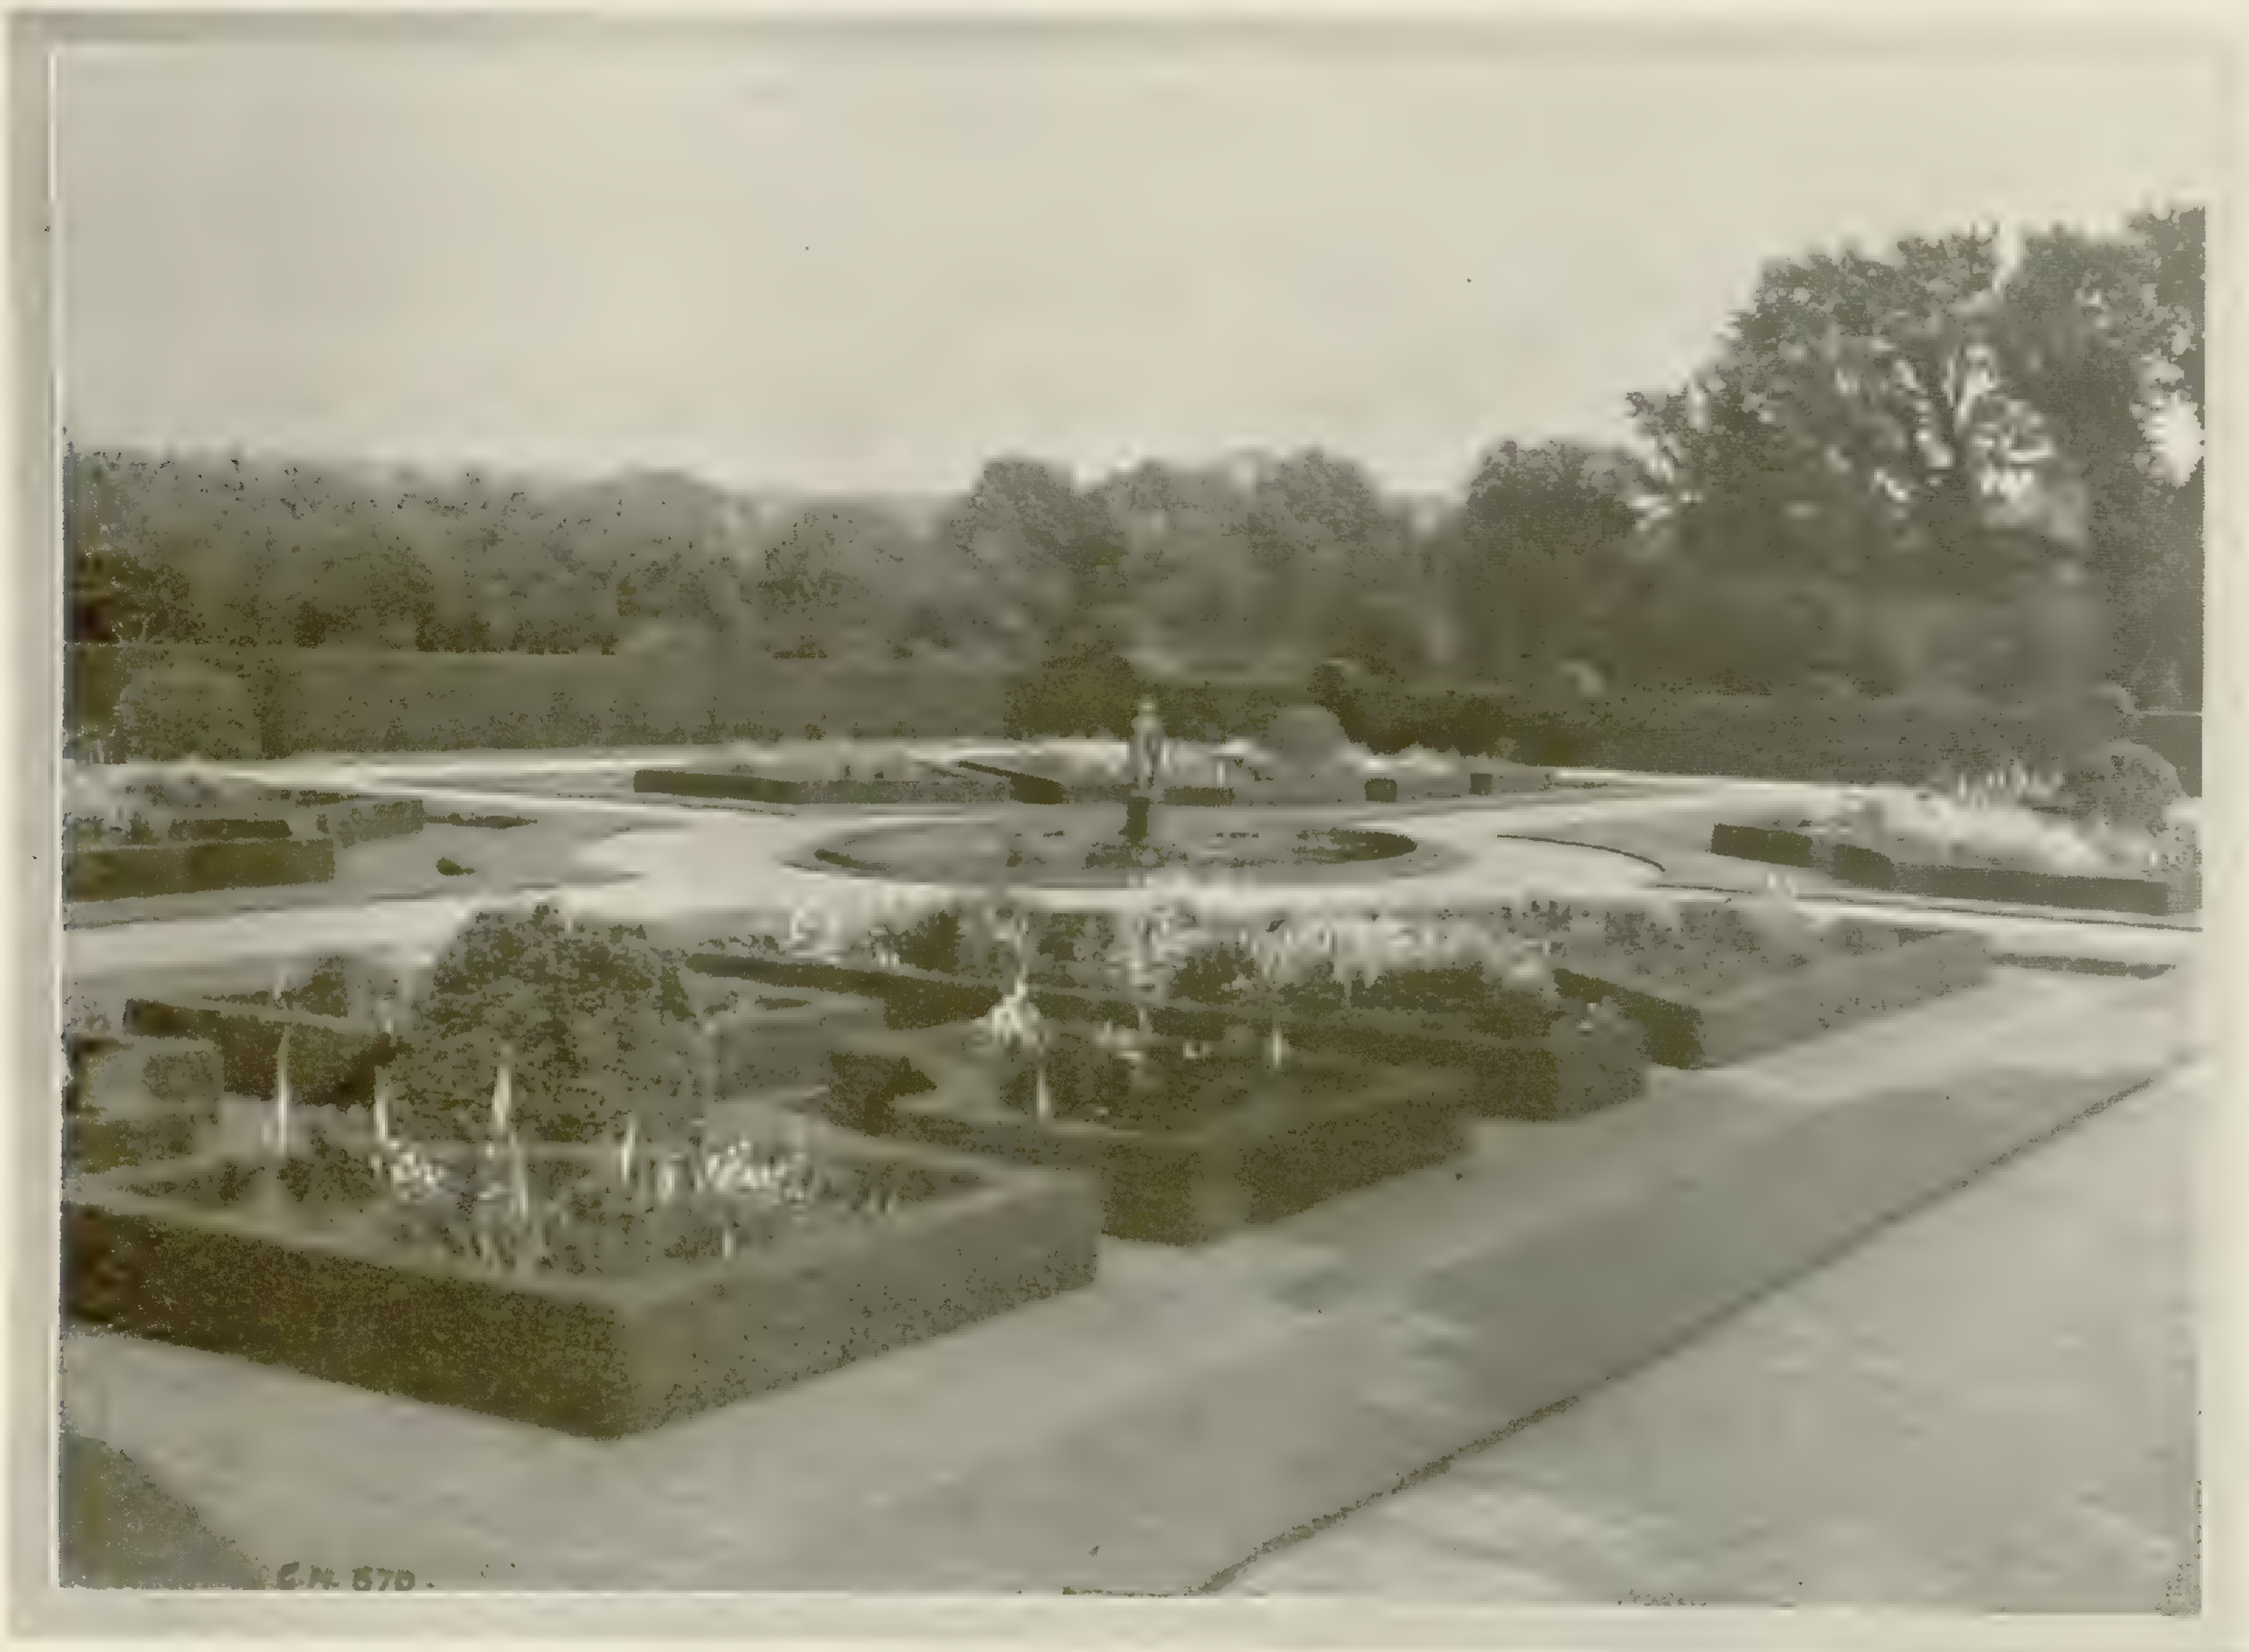
The gardens of Swaylands House are extensive, tasteful, and admirably kept, and they possess, in addition to their many other advantages, features that are quite unique, and of these the rock garden, magnificent in plan and execution, is the most noteworthy. The stately mansion occupies a broad plateau in the higher part of the grounds, and, like so many other of the great houses in the Tunbridge Wells district, commands a wide-spreading, highly-diversified, and beautiful landscape. The plateau has for its southern boundary a supporting wall of grey sandstone, and extending the whole length of this is a narrow border devoted to hardy perennials. The length of the wall and its parallel border is probably a fifth of a mile, and this point assumes some importance when one looks over the wall and sees the wide border at its foot furnished with the finest of the hardy perennials now at the command of the cultivator. The latter border impresses one more strongly when seen from one end of the broad walk alongside it. The length of the border is shown in the accompanying illustration, but owing to the strong sunlight at the time the photograph was taken, and the proximity of several large trees, the lighting is not all that one could wish.

FLOWERY CLIFFS IN ROCK GARDEN, SWAYLANDS HOUSE.

At the eastern end of the plateau there is a broad expanse of lawn, in part devoted to garden games and in part to the growth of roses, which form a distinct and pleasing feature. Here weeping standards are employed, both in beds and singly, with good effect, and one may see specimens of the more popular kinds of a size that is not at all common. The cultivation of rambling roses in standard form has received attention here for a considerable period, and it is probable that when the history of weeping standards comes to be written, the historian will find that Mr. R. Hosier, the able head gardener, was one of the first to recognise the value of weeping standards, if not the originator of them. Rumour credits him with their origination, and the specimens under his charge prove to demonstration his long and thorough acquaintance with them. Dwarf roses are also admirably grown in this part of the grounds, and singly on the lawn, and in the fringe of trees that shelter the mansion from the north-east are well-developed examples of many choice trees.

Proceeding down the slopes towards the south an entrance is found to the rock garden, which is so enormous in its area, so distinct in its features, and, moreover, so rich in its attractions, that one quickly appreciates the great difficulty in conveying to those who have not had the pleasure of seeing it an adequate idea of its characteristics. There should be no difficulty in making it quite clear that the whole of the rock garden has been planned and constructed by Mr. R. Hosier, with, of course, the aid of such suggestions as may have been made by his employer, or that the task which has been accomplished is one of which both the owner of Swaylands House and his gardener have full justification for indulging in a strong sense of satisfaction. The general view of the rock garden will give some idea of its scope; but, unfortunately, for the purpose of photography the dark grey rocks and the green leafage have much the same tone value, and, consequently, in the illustration the rocks do not stand out quite so clear and distinct as could be desired for graphic purposes. Along the lower side of the rock garden is a fine sheet of water fringed with suitable moisture-loving vegetation. On the far side of the water is a broad walk, bounded on one side with rockwork, and if readers will compare the rocks, which rise to a height of fifteen or more feet, in the second of the two illustrations, with the foreground of the first, they will be better able to understand how large is the area over which the garden extends. Broad walks run in all directions, in accordance with a well-devised plan, and are skilfully flanked with rock, in some cases rising to a height of twenty feet, and so arranged as to afford a good foothold for the plants, trees, or shrubs with which they are furnished. In some parts the walks open out, and low slopes are provided for the cultivation of the choicer alpines, of which there is a large collection. Elsewhere the walks assume the appearance of narrow ravines, with great masses of rock frowning ominously overhead; and here and there one meets with large caverns, and on the moist walls forming the entrance may be found hartstongues and other ferns that thrive in cool, moist, dark positions.

In traversing the huge lengths of walk within this remarkable garden one is not only interested in the skill displayed and the success achieved in giving it a truly naturalistic appearance, and providing for the requirements of the varied forms of vegetation, but surprised by the enormous size of the greater proportion of the pieces of rock used. Blocks weighing from one to two tons are quite common, and there are numbers of others weighing from three to nine tons, such weights not being very easy to hoist to a considerable height, and place in their proper positions. Mr. Hosier does not, however, appear to have experienced any great difficulty, for he regards what has been done in the creation of this great feature a very ordinary accomplishment. The garden is highly attractive from the opening days of spring until the trees assume their autumnal tints; but it is seen at its best when immense breadths of arabis and alyssum, that the sterner precipices are veiled with, are at the zenith of their floral beauty. This has not as yet been my pleasure, but I trust that some day I may be able to record its accomplishment.



OLD ENGLISH FLOWER GARDEN AT PENSHURST PLACE, TUNBRIDGE WELLS.

Leyswood.

Especially picturesque are the grounds of Leyswood, Mrs. Temple's charming residence, which is situate near Groombridge, and the great masses of rock that crop out here and there, and especially in the large area devoted to conifers, suggests a scene in the highlands of Scotland rather than the grounds of a private residence in a southern county of England. Very beautiful is the scene that presents itself to the visitor as he enters the grounds by way of the carriage drive that passes through the pinetum, of which a small portion is herewith illustrated. To the right are masses of rock, surmounted by beeches and other of the strong-growing deciduous trees; to the left is a broad rocky bank rising to a great height, and increasing in grandeur as it comes opposite to the mansion, where the drive passes through a comparatively wide ravine to reach the plateau beyond. Between the drive and the rocks to the right the broad area is devoted to choice coniferous trees, and here may be seen magnificent specimens of Abies Albertiana, A. pungens glauca, Cupressus Lawsoniana, Picea nobilis, and other of the finer kinds. On the rocks to the left rhododendrons luxuriate, and seedlings in considerable numbers have effected a lodgment in the crevices of the rock, where they grow freely, and produce a rich display of colour early in the summer. Here also are many other beautiful shrubs, with a goodly number of deciduous and other trees. The mansion, of which one side is seen through the trees, stands on a broad plateau, and on the far side is a large wood, and in the centre of this is a geometric flower garden in which displays of great beauty are annually produced. Many are the finely developed trees on the margin of the flower garden, and the tree lover, as well as those who appreciate the charm of summer flowers, will find plenty to interest them within this garden, that if not exactly unique, is so distinct from the flower gardens usually met with, that it may be so spoken of without any considerable departure from exactitude of description.

One might linger long among the trees and flowers, and also among the dark grey rocks, but the "glass" at Leyswood forms a great, and certainly interesting feature. Not to have a walk through the numerous richly-furnished glass houses would be to miss one of the greatest attractions a gardener could well have. There are orchid houses, plant stoves, greenhouses, and structures devoted to grapes, peaches, melons, and tomatoes that one might be excused were he to indulge in a few statistics. I shall, however, resist the temptation to do so, and say at once that the structure which most strongly appeals to me is the magnificent camellia house, filled from end to end with splendidly developed specimens that annually yield freely of their handsome flowers. This house has a length of 100 feet, and a width of 25 feet, and within its portals are represented upwards of sixty of the finest varieties that have been introduced to cultivation. This collection may certainly be described as unique. I certainly so regard it, but if there is another private garden containing so large a collection of specimen camellias I should like to hear of it. Orchids are so extensively grown as to necessitate several structures for their accommodation. In one of these may be seen 2,000 or more cattleyas and laelias in splendid health, for Mr. Bristow is not less successful in the cultivation of these as of the many other plants under his care. Odontoglossums are sufficiently numerous to occupy two or three houses, and these include large numbers of superb forms. Cypripediums occupy much space in other structures, for of these the collection is large, and, it may be added, in the finest condition. Miltonias, masdevallias, and dendrobiums are not less noteworthy in their way, and disas are grown exten-

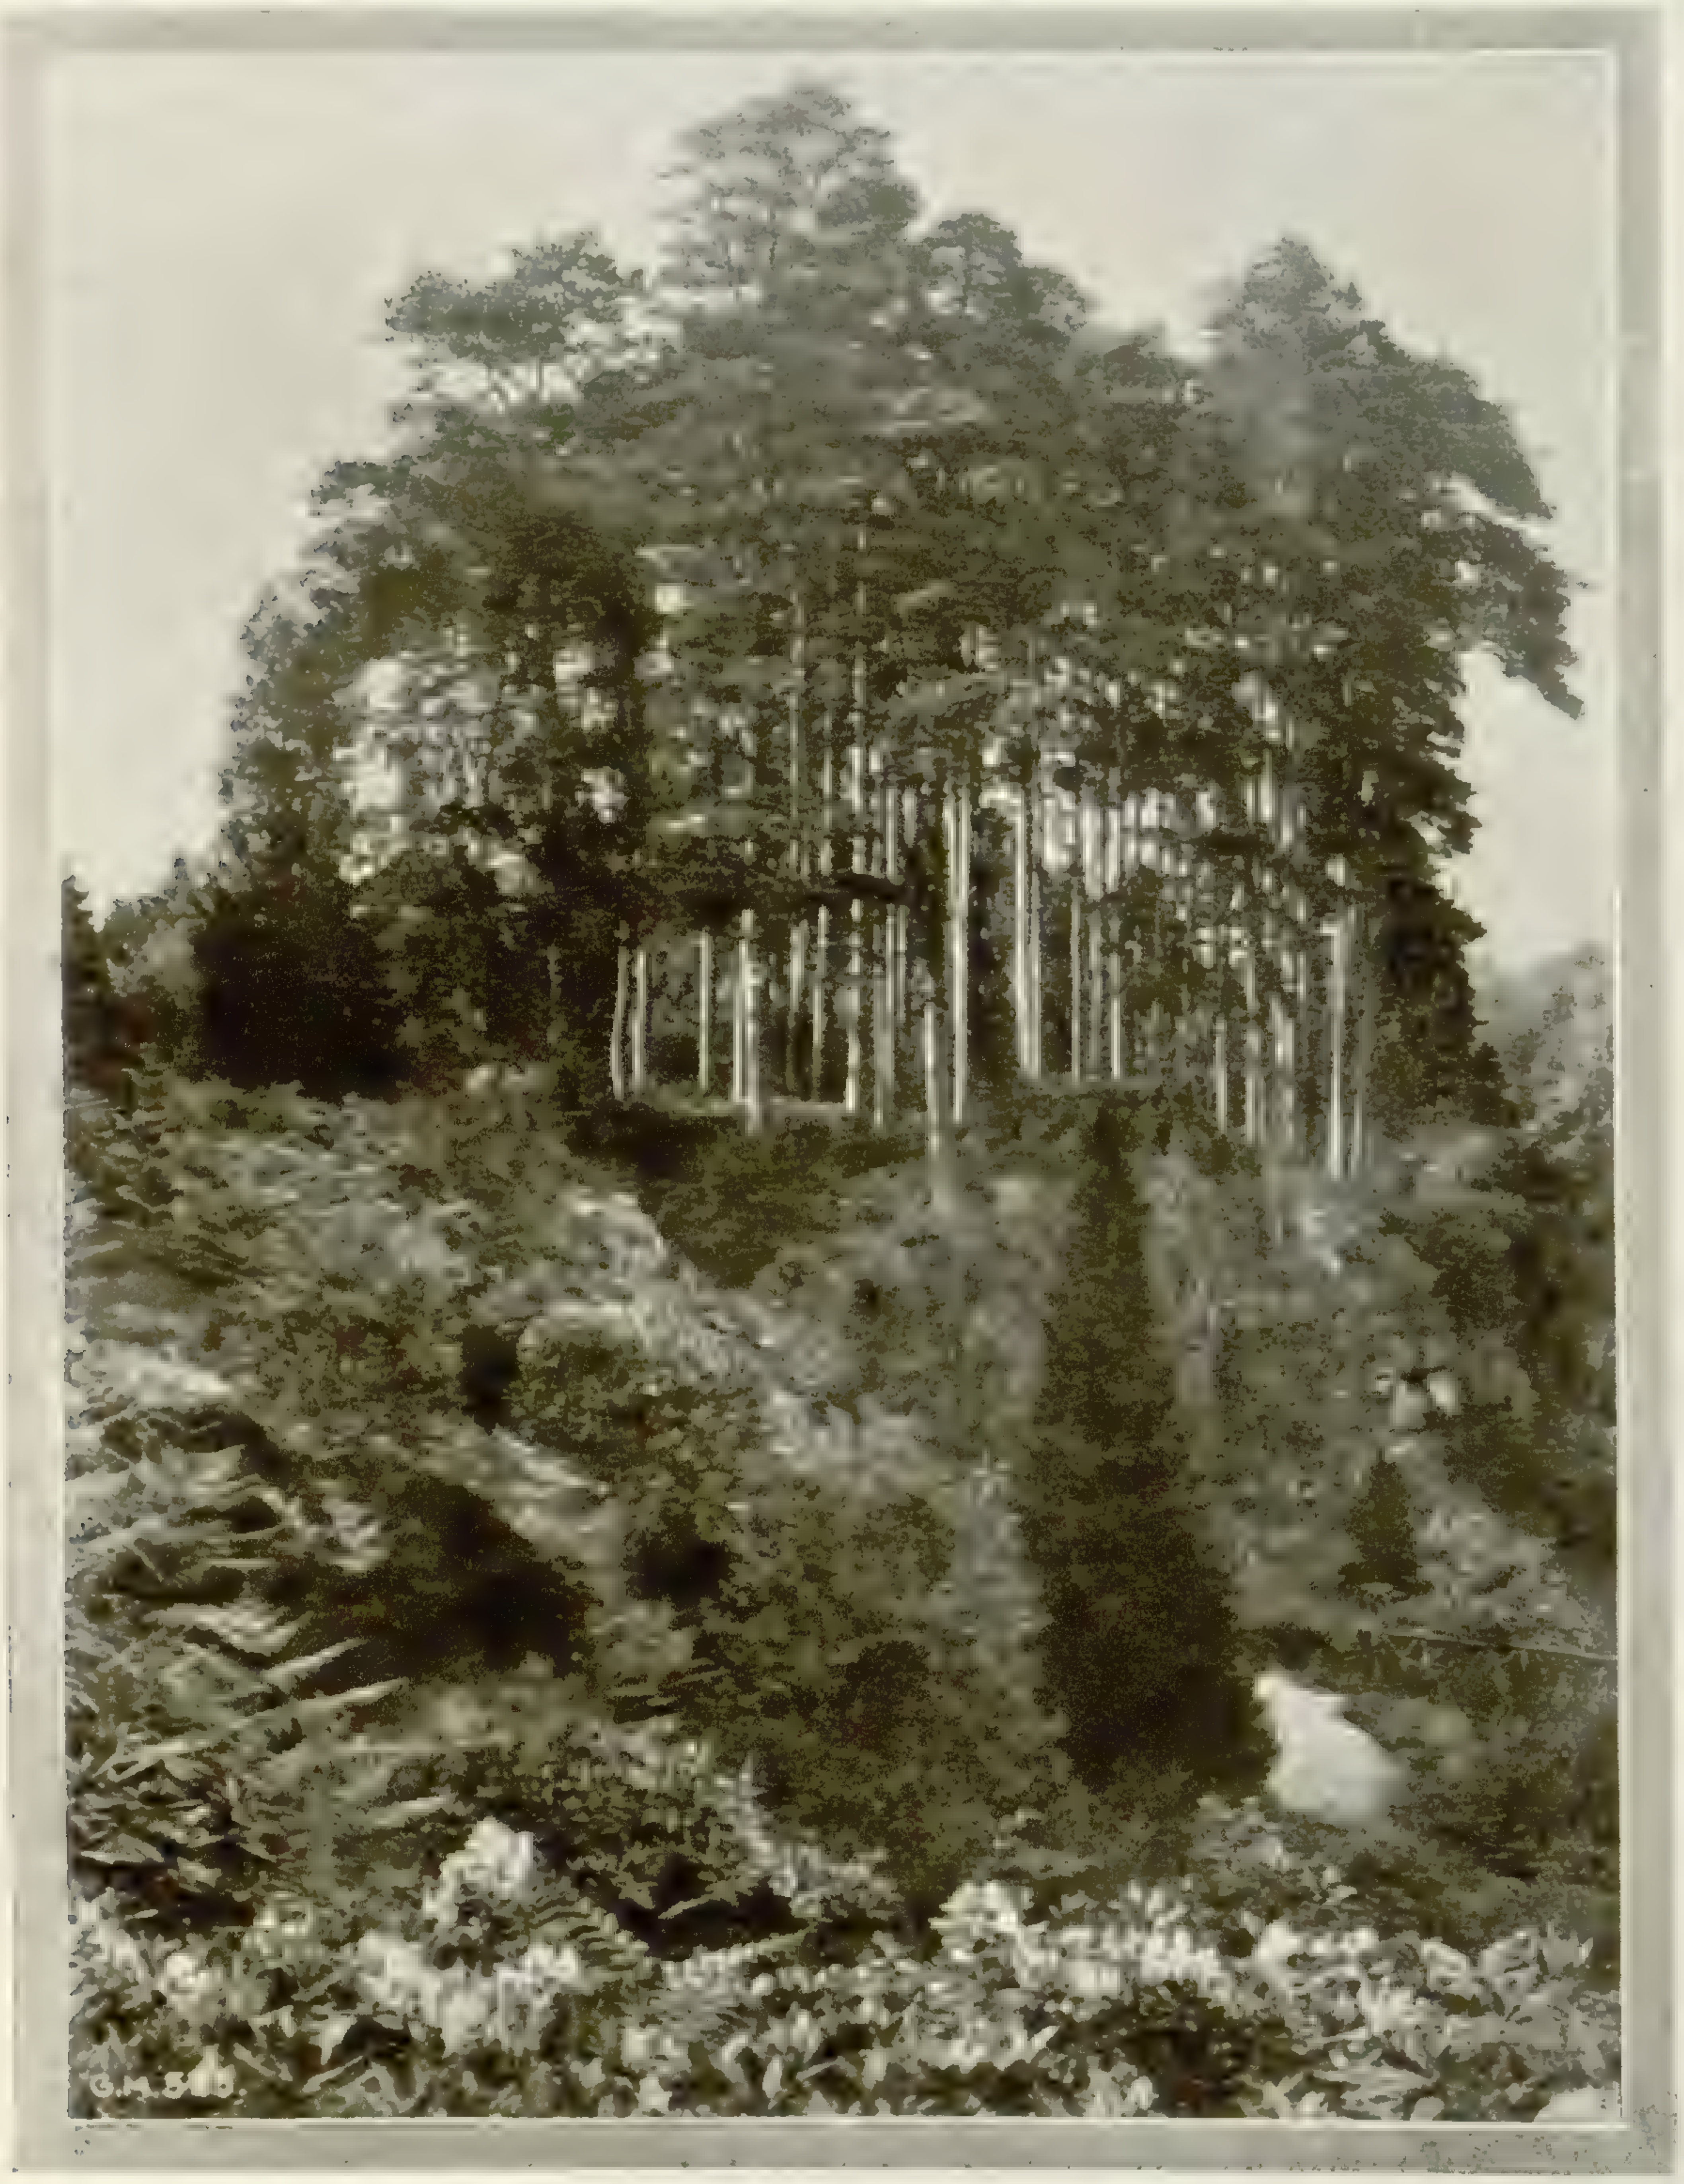
LEYSWOOD, TUNBRIDGE WELLS.

sively, and with quite exceptional success. The spacious structures devoted to nepenthes, to caladiums, to miscellaneous stove plants, and to palms and bananas contain much that is of interest, and afford proof of cultural skill of a high order. Not less evident is the cultural skill which Mr. Bristow brings to bear upon the fruits under glass, and as the splendid crops of Muscats and other grapes, of peaches and nectarines, and of figs are called to mind, the desire arises to refer to them in detail, but the space available prevents practical effect being given to that desire.

Glen Andred.

Having undertaken a rather wider range of visits than was possible of accomplishment within the twelve hours that had been allotted for them on the day that Glen Andred was included in the programme, I was not able to see so much of its beautiful gardens as I could have wished. Although, to quote from a well-known and somewhat hackneyed poem, "The shades of night were falling fast" when I reached Glen Andred, I managed to obtain a few good photographs, and see enough of the gardens to recognise the fact that the Rev. E. H. Boardman takes a keen interest in them, and that his gardener, Mr. J. Legg, is a skilful cultivator. The residence and its grounds are within a short distance of Leyswood; some writers would probably describe them as within a stone's throw, but as that would hardly be exact, it is better to leave the distance an unknown quantity, or make a guess that the entrance lodges are a quarter of a mile apart. In general character the grounds of the two residences have much that is in common. The mansions stand on broad plateaux in the higher parts of the grounds, and command views that are certainly unsurpassed both for their wide range and extreme beauty. They have also bold masses of rock cropping up in various parts of the grounds, and the open valley, devoted to conifers at Leyswood, has its counterpart at Glen Andred in a charming glen, of which the dominant feature is the great group of Scots firs herewith illustrated. Through this glen runs a stream of water, which is here and there widened out to provide accommodation for choice water lilies and other aquatics. On the bold rocky banks are masses of rhododendrons, and on the lower banks in the open spaces suitable sites have been found for a goodly number of rock plants. Within the glen also have been planted large numbers of choice deciduous and evergreen shrubs, and one might well spend several hours in exploring it, and enjoying the many objects of interest with which it is beautified. From every turn of the walk running through the glen the remarkable group of Scots firs presents a charming effect, and from no point does it more greatly impress one than when seen from the windows of the mansion which stands at the head of the glen. In the grounds around the mansion are borders of herbaceous plants, masses of roses, and not a few specimen conifers, more or less noteworthy, the most remarkable examples being, perhaps, those of Abies Albertiana, Cupressus Lawsoniana, and Wellingtonia gigantea.

George Gordon.



A REMARKABLE GROUP OF SCOTS FIRS AT GLEN ANDRED, TUNBRIDGE WELLS.

PRIMULA MINIMA.

To see a good plant of Primula minima, or even a good illustration of this miniature primrose, is sufficient to set one afire to possess and to cultivate with success such a charming little flower. It is not so easy to do either, but the acquisition is by no means so difficult as the cultivation, and the number of those who have succeeded in keeping this primrose in a happy and healthy condition for a few years in our British gardens is limited indeed. It is almost impossible to give it the conditions it enjoys at home; and, above all, the short and hard-growing grassy vegetation in which it flourishes at home is practically impossible of attainment in our land. At home it grows among miniature grasses, but when we bring these to our climate they grow out of recognition, while the primula does not increase proportionately, with the result that the primrose is choked out and perishes, although one can succeed no better, if as well, if we leave it unsheltered and unsurrounded by this grassy growth.

I have just been refreshing my memory with a look at the coloured drawing of this primrose in Wooster's "Alpine Plants," and, although the colouring is not very faithful, a peep at the illustration is sufficient to imbue one with the desire to repossess this beautiful little plant from the high Alps of the South of Europe.

As it grows from 7,000 to 8,000 feet above the level of the sea, we cannot be expected to give it exactly the conditions under which it flourishes at home. Its height is only about an inch and a-half, while its flowers, which are pink, violet, or rarely, white, are sometimes quite an inch across. It should have a compost of loam and grit, and should be kept moist—conditions which, however, would send to grossness the plants among which it grows at home. Plenty of stones about its crown will be most helpful, and will to some extent, compensate for the natural shelter it receives at home. On the other hand, these stones become hot in the sun, and this suggests the provision of at least partial shade, which can best be secured by means of a large stone to shield the primrose from the strongest sun.

It has often been remarked that the hybrids between this fairy primrose and others are by far more satisfactory than P. minima itself, and that such forms as P. Floerkiana and P. Fosteri are both more easily grown and are more appreciated in the garden.

S. Arnott.

Sweet - scented Daphnes.—Daphne indica (odora) can be procured in two forms, one having red, the other white flowers; in both instances these are deliciously scented, and for this reason they are commendable subjects to include among spring-flowering greenhouse plants. A strong point in their favour is that when in flower they may be removed indoors, and if placed in any well-lighted room they retain their beauty and fragrance for some considerable time. There are also variegated forms, with flowers quite as sweetly scented as in the type.—Thomas Smith, Walmsgate Gardens, Louth.

THE WEATHER IN 1908 AT BUXTED PARK.

The year just ended cannot be looked upon as one of the best, though from a horticultural point of view we have had many worse. The early spring was anything but favourable to growth, but yet we had fair crops of fruit, though stone fruits were below the average. April and August were the two worst months. January was by no means so cold as we experience it sometimes, though on two successive nights we registered 23 degrees of frost. On the whole, however, it was a dry month, for, with the exception of the heavy snow storm on the night of the 7th, which did such damage to trees and shrubs—equalling when melted more than two inches of rain—and though rain fell more or less on fifteen days, the total amount, including the snow water, was only 2.41 inches. Rain fell on 21 days in February, the total fall being 1.41 inches. The most frost registered during the month was 11 degrees on the 13th; the warmest night was on the 21st, when the temperature did not fall below 44 degrees.

The weather in March was very peculiar, for though rain fell on 24 days, the total amount did not reach three inches. There were some very cold nights, notably on the 12th and 15th, when 14 degrees of frost were registered. The highest maximum reading was on the 24th, when the temperature rose to 57 degrees in the shade. The early part of April was dry, and the ground in good condition for seed sowing. Up to the 18th of the month only .38 of an inch of rain fell, but from that date to the end of the month the weather was winterly, heavy snow storms on the 23rd and 25th being accompanied by sharp frosts at night, which did considerable damage to the fruit blossom. Rain fell more or less on 14 days, the total fall being 2.11 inches. The warmest day was on the 30th, when the temperature reached 64 degrees in the shade. May was a fine month, for though rain fell more or less on 13 days, amounting to 1.79 inches, there was some very warm weather. On the 2nd the temperature reached 78 degrees in the shade, and on the 19th and 31st 81 degrees, which helped vegetation very much. There was only one night in which the temperature fell below 32 degrees, and that was on the 24th. In June we had some remarkable weather, the average maximum temperature in the shade for the first four days was 84.50 degrees, while that for the whole month was 73.25 degrees. On the 4th the temperature reached 92 degrees in the shade, while on the 7th it fell to 35 degrees. The minimum average temperature for the month was 46.26 degrees, or two degrees higher than that of May. The rainfall was 1.28 inches, rain falling more or less on nine days.

The fine weather of the latter half of June continued until July 7. The first three or four nights were remarkable for the fine display of the Aurora Borealis, so seldom seen during the summer months. From the 7th to the 19th we had showery weather, afterwards fine until the end of the month. The total rainfall was 3.51 inches. The average maximum temperature was 75 degrees, and minimum 49.22 degrees. In August, with the exception of a slight shower on the 5th, no rain fell until the 20th, but from that date to the end of the month 5.51 inches were registered, the heaviest fall being on the 23rd. This was the wettest August since 1860, when the fall in August of that year was 5.84 inches, or just a third of an inch more than in 1908. In 1852 the rainfall for August was 6.01 inches, and in 1848 6.05 inches, which were the wettest Augusts in this district since 1843 of which I have a record. The average maximum temperature for the month was 72 degrees in the shade, minimum being 45 degrees.

Coming to September we find the rainfall was slight, being 1.19 inches, which fell on thirteen days, this being considerably below the average for the month. The average maximum temperature was 69 degrees in the shade, the hottest days being on the 18th and 30th, when the temperature reached 79 degrees. The average minimum was 42.20 degrees, the coldest night being on the 13th, when there were 3 degrees of frost registered. Taking the month altogether it was a very pleasant one. The last three days were warm and sunny, while the night of the 28th was the warmest during the year; the temperature not falling below 61 degrees. The fine weather experienced during the last few days of September continued well on into October, for with the exception of a slight shower on the 9th and 16th no rain fell for the first three weeks. The day temperature, too, during the early part of the month was exceptional; for the first four days it averaged 79.50 degrees. The total rainfall for the month was only 1.73 inches. There have only been six times during the last 65 years when the rainfall for October has been less than during the last. One of these was after the wet summer of 1879, when the total rainfall for October in that year was only 0.77 inches, and for the two succeeding months 2.30 inches. It will be remembered that the winter of 1879-80 was very severe, frost commencing in November and continuing more or less until February. The maximum temperature for October was 64.13 degrees, and the minimum 42.29 degrees. With such weather it was no wonder that vegetation remained active. With us no frost was registered until the 22nd, and as the weather had been fine, tender vegetables and choice flowers were to be had in abundance outside.

The first ten days of November were dry, and, though the nights were somewhat cold, it was not until the night of the

LAKE IN PLEASURE GROUNDS AT BROOM HILL, TUNBRIDGE WELLS.

9th that we experienced any severe frost; the temperature then fell to 19, or 13 degrees, the next night there was 10 degrees of frost, which put an end to all outside flowers. On the whole, November was a fine month, the rain amounting to 1.56 inches, and this fell on seven days. Fog here was very prevalent during this month, and on eight days the equivalent of .01 inches of rain was registered.

Up to the 21st the weather in December was dull and damp, and the wind southwards. The wind then changed to the east, and the temperature fell considerably, the maximum readings being only just above freezing point, and this continued until the 30th. On the 29th the highest maximum temperature was 24 degrees or 8 degrees of frost, with a very keen wind blowing from the east. We have not had such a cold day since January 18, 1881. On the night of the 29th we registered 29 degrees of frost, and on the 30th 28 degrees, which are the lowest temperatures for several years. The fall of snow on the 29th averaged about six inches, but with a strong wind there were drifts in places. The average maximum temperature for the month was 44.18 degrees, and the minimum 32.10 degrees. The warmest day was on the 13th, when the temperature reached 55 in the shade, and the coldest night was on the 29th, when the temperature fell to 3 degrees. The rainfall for the month was 3.35 inches, and that for the year was 28.80 inches, which is about an inch below the average. The highest reading of the barometer was on the 31st, when the mercury stood at 30.75, which is the highest reached since 1905. The lowest reading was on the 11th, when it fell to 28.40. December in 1908 will be remembered for its fogs, for during the whole time I have been here these have not been so frequent or so thick. On the 31st the temperature changed about 7 a.m., and a thick fog set in, the temperature rising sharply until the maximum was 40 degrees. So closed the year of 1908.

H. C. Prinsep.

THE RASPBERRY.

The raspberry takes a prominent place amongst hardy small fruits, and deservedly so, for it makes one of the best preserves, and a most excellent tart, and, moreover, it is perfectly hardy, comparatively easily cultivated, and a heavy cropper, affording a good succession of fruit. Another valuable attribute is its late season of flowering, which enables its blossoms to escape the spring frosts that are often disastrous to the flowers of the strawberry, currant, gooseberry, etc.

I have remarked that this fruit is comparatively easy of culture, but from this it must not be understood that it can be successfully grown without any trouble. It will nevertheless succeed in most garden soils, though that most suitable for it is a good deep loam, neither very heavy or very light. This should be deeply trenched, preferably in the manner known as bastard trenching, by which means the surface soil —usually the best—is left upon the surface. After trenching is completed, a dressing of farmyard manure, more or less heavy, according to requirements, should be dug in a spit deep. It is important to do this part of the cultivation thoroughly well, as the length of time a plantation will last in good condition depends greatly upon the way it is done. Upon very porous or light soils it is advisable to choose, if at command, a partially shaded situation.

For planting purposes strong, well-rooted canes should be secured, and planted as early as is practicable in autumn, so that fresh root action can take place, and the plants become established before winter sets in. Of the several modes commonly adopted of arranging and training the plants, that of placing them in rows six feet apart, and two feet asunder in the rows, and training the canes upon horizontal wires, is the best. The older method of planting in rows five feet or six feet apart, with the plants about four feet asunder in the rows, and of tying three or four canes from each plant to firmly secured upright stakes, still has its advocates, as has also that of planting in a similar manner to the last-named, allotting each plant four canes, and arching two of them in one direction and the others in the opposite, and fastening their points to the points of canes of the adjoining plants, thus making a succession of arches along the rows. Next to the practice sometimes carried out of merely thinning and shortening the canes, without using supports of any kind, this is the most inexpensive method, while it also affords the young shoots free space in which to develop.

The raspberry being a surface-rooting subject, and a lover of root moisture, is greatly benefited by being mulched with stable litter during the summer, and watered with farmyard liquid. A good dressing of farmyard manure lightly forked into the soil early in spring is likewise of much benefit. Failing this, top-dressings of suitable artificial fertilisers should be afforded. These are easily applied, and are beneficial, but they are not—at least with us—so valuable for the raspberry as good farmyard manure, which is nourishing, but also acts as a good rooting medium. As soon as the young growths have made sufficient advance to enable one to ascertain which of them will make the best canes, sufficient of the most suitable should be selected for fruiting, and the remainder cut out. In attending to this it should be remembered that the crowding of growths works serious evils, both by causing weak growth and preventing the canes from perfectly maturing, as well as unnecessarily exhausting the soil. Once the fruit is gathered the old canes should be cut out and the young ones loosely looped to their supports.

By the end of February the canes should have been secured to their supports, those upon horizontal wires being eight inches apart, and those having stakes as supports should be drawn together by strong ties, but not closely enough to cause crowding. This should be followed up by shortening the canes in agreement with their strength and the manner of training. Newly planted canes should be cut down at this time to within nine inches or a foot of the ground.

Autumn-fruiting raspberries are especially useful in the kitchen; they are best planted in rows running north and south, and should have their shoots, which are usually far too freely produced, well thinned out in early summer, the strongest being selected to carry the crop. As these bear fruit upon the current year's growth all the canes should be cut down to the ground level early in March, but other details of culture should be carried out as directed for summer-fruiting varieties.

T. Coomber.

The Hendre Gardens.

Everyone interested in a garden should obtain a copy of the Alphabet of Gardening, by T. W. Sanders. Thoroughly practical information is given as to soils, manures, seed sowing, planting, potting, budding, pruning, grafting, forcing, hybridising, etc., with explanatory diagrams. Price 1s. 6d. net, by post 1s. 9d.; cloth, 2s., by post 2s. 3d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London

JANUARY COLOUR.

A poet has called January

"Sad month of drab and dun,
Sleet grey, and icy white
Of beaten snow;
Month without glimpse of sun,
And dearth of happy light,
When naught can grow."

but he was, assuredly, no gardener. Every possessor of trees and shrubs or herbaceous border, can trace the coming spring, and note the swelling bud and deepening tint of branch. All the same, it is best for us so to plant our pleasure grounds that plenty of colour will be visible during January, when no left-over flowers can possibly have been spared to us by November and December, however genial.

Gold tells wonderfully in the landscape, and gold we may have in plenty. The golden privet is the brightest of shrubs, and keeps its foliage well in sheltered localities or the southern counties; in many parts of Sussex it can be safely used for a front garden hedge, for example. Against a white or gray wall its hue is of such value that it may be trained out as though it were more rare.

The variegated golden euonymus strikes a deeper note of colour, and is a great deal more robust. Perhaps its best form is that of a rounded pillar, well clipped, and therefore so dense as to offer a close surface to defy cutting winds: low globe-shaped bushes are pretty on a lawn or by the house steps; porch shelters or arbours can be completely formed of it.

The snowberry tree, Symphoricarpus racemosus, is always a noteworthy feature of a January landscape; there are fewer berries than during November, but quite enough to weigh down the branches, so that they gracefully sweep the grass, and what a brilliant ivory-white the mass appears under even faint gleams of sunset! A background of aucubas is always a cheerful feature, one to be placed behind the snowberry advisably, or close to clumps of the stately pampas grass, which gives an ornamental effect for so long a period. Ivies are among the colour producers of January. A red-brick wall climbed by any silver variegated variety is a joy to look upon, especially after being washed by winter rains or after having been buried beneath cleansing snows. Gold variegated ivies light up gray walls or fences admirably, and a whole house-side or turret, clothed in the cream blotched version even of the common ivy, Hedera helix variegata, proves a welcome feature. Then there is rich colour, of a sort, to be gained from Hedera helix purpurea, one of the best of all climbers against white walls, and the gay green of Hedera helix algeriensis offers yet another feast for the eye.

Yes, green is a colour of which we must make the most at this season, instead of regarding it as merely foliage-tint to show off red and pink, blue, gold, and violet blossoms later. It is for its verdant beauty of hue that the common laurel is so valuable, the ordinary glossy euonymus also. The gorse has its own merits in the garden scene, even when it bears none of the seldom absent yellow flowers; the rhododendron's solemn green serves to contrast with more vivid leaves.

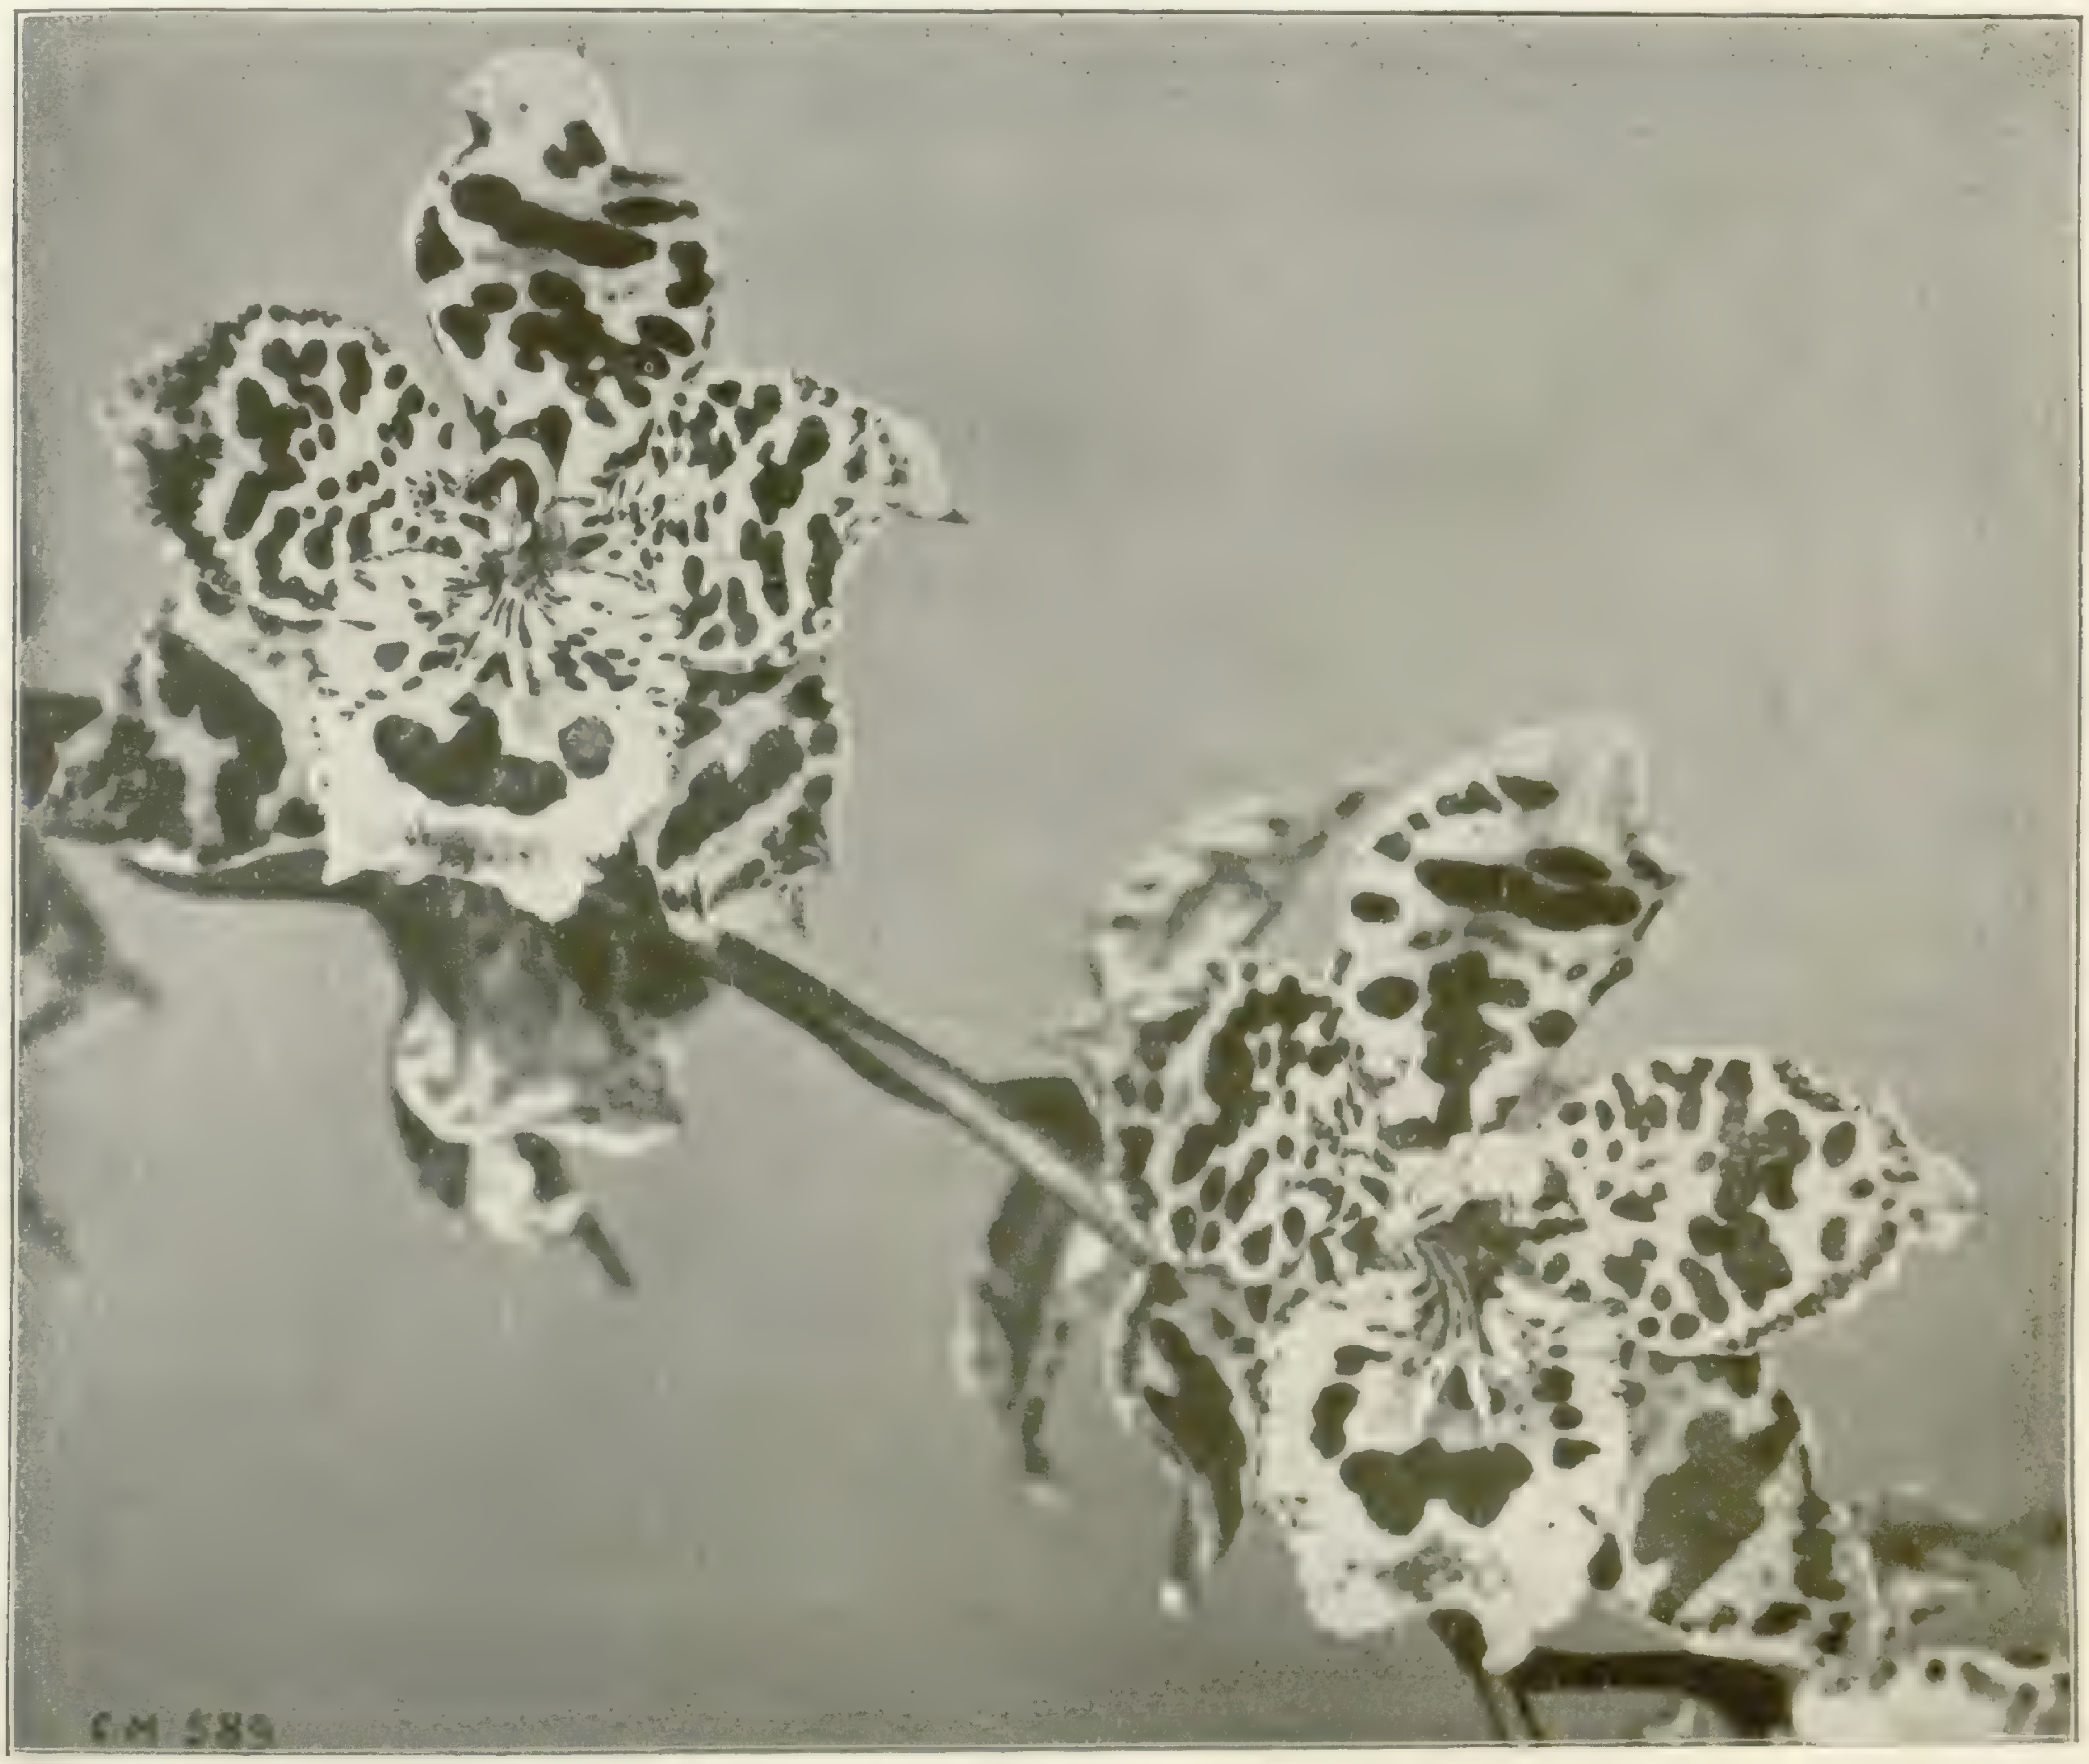
Then Lonicera japonica aureo-reticulata is a gay climber that is seen at its best when closely grown in pillar fashion up verandah pillars; Berberis aquifolium is scarcely ever without ruddy warmth. Golden firs and silver box increase our indebtedness to the shrub family. Perhaps the very brightest of all January colours is that of the vermilion-berried fire thorn, Cratægus pyracantha, for which reason it should be lavishly employed in all gardens, and guarded, if necessary, by black cotton from the visits of too many birds. The best berried hollies may be similarly protected. Hawthorn and Rosa rugosa fruits shine out, too, with welcome effect, while whole stretches of ground can be cloaked by the spreading branches and crimson berries of the useful cotoneasters.

M. H.

NEW PLANTS, ETC.

ODONTOGLOSSUM MAGALI SANDER.

A very beautiful and finely formed odontoglossum, obtained by crossing O. Rolfeæ with O. Adrianæ F. K. Sander. The flowers are of large size, and the ground colour is creamy white, freely mottled and blotched with bright rose, and with numerous blotches of bright purple-brown. The white lip has a golden crest, and is marked with rose and red-purple. F.C.C., R.H.S., December 22. Messrs. Sander and Sons, St. Albans.



ODONTOGLOSSUM MAGALI SANDER.
Exhibited by Messrs. Sander and Sons at R.H.S. Meeting, December 22, 1908, when a F.C.C. was conferred upon it. Flowers marked with rose and purple-brown on a white ground.

CYPRIPEDIUM ELATIOR.

A very pretty orchid derived from C. Leeanum and C. Baron Schröder. The influence of C. Leeanum is not so marked as usual, while the violet-purple colouring of C. Baron Schröder is very evident. The shape of the latter is also maintained. The white dorsal sepal is marked with rose-purple, and the lip and petals are shaded with violet-purple. A.M., R.H.S., December 22. Messrs. J. Veitch and Sons, Chelsea.

APPLE WILLIAM CRUMP.

This is said to be a good dessert variety, obtained by crossing Cox's Orange Pippin with Worcester Pearmain, but we were unable to find examples of it for description. A.M., R.H.S., December 22. Mr. W. Crump, The Gardens, Madresfield Court.

MUSSÆNDA ERYTHROPHYLLA.

A handsome shrub which has long been known to science, having been described in 1827 from specimens collected by Thonning on the Gold Coast; but the oldest of the specimens in the Kew herbarium were collected by Mr. Gustav Mann early in 1862 in the Cameroons, at an elevation of between 3,000 and 4,500 feet. It has since been collected by several travellers in various localities ranging from Sierra Leone to Angola, and eastward to Uganda, and it is described as forming one of the most striking objects on the outskirts of the forests. The flowers are produced in terminal cymes, and are bright red, the stalks clothed with long crimson hairs. One or more of the calyx lobes in each cluster of flowers expands into a leaf-like structure about five inches in length and four inches in breadth, and of a brilliant crimson hue. These brightly coloured leaf-lobes constitute the chief attraction of the shrub, and Mr. Watson describes them as "being quite as effective as the bracts of the poinsettia, and they appear to be quite as persistent." Bot. Mag., t. 8222.

MECONOPSIS SINUATA LATIFOLIA.

A beautiful and rare form of fairly free growth with broad leaves, and bearing bright blue flowers. Seeds were collected by Lieut.-Colonel H. Appleton in North Kashmir, where it is rare, and these were sent to Kew in February, 1906, and in June of last year the plants raised from them flowered. Lieut.-Colonel Prain suggests that the treatment suitable for Meconopsis aculeata, which succeeds best in moist, shady places, planted in a peaty soil, should be adopted for this form also, which loses its crown of leaves during winter. Bot. Mag., 8223.

PYRUS SINENSIS.

An interesting pear that has long been in cultivation in Northern China and Japan, and, according to Siebold, several distinct varieties have been raised in the last named country. The tree attains a height of between 30 and 40 feet, has white flowers, and these are succeeded by brown globose fruits from two to three inches in diameter. Bot. Mag., t. 8226.

BERBERIS YUNNANENSIS.

A handsome species from Western China, forming a compact bush from two to three feet in height, and bearing a profusion of pale yellow flowers. This species was first discovered by Delavay in 1885, near Lankong, Yunnan, at an altitude of 10,000 feet. Since then it has been collected in Western China by Mr. E. H. Wilson, who also found in the same region the closely allied species B. macrosepala, which previously was only known from the Sikkim Himalaya. A valuable addition to the cultivated barberries. Bot. Mag., t. 8224.

CORYTHOLOMA MACROPODUM.

An interesting gesneriad with bifoliate stems and medium sized cinnabar-red flowers, borne in clusters of five or six. Bot. Mag., t. 8228.

ERIA HYACINTHOIDES.

An interesting Javan orchid, originally described by Blume in 1821 under the name of Dendrolirium hyacinthoides. It is free in growth, and produces, in May, elegant spikes of white oflwers. Bot. Mag., t. 8229.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

SEASONABLE NOTES.—Cleaning the plants is one of the principal items to be attended to at the present season of the year. It frequently occurs that the prevailing conditions outside are of such a nature at this season, that outside work is at a standstill, and so where labour is restricted the opportunity thus afforded should be made use of, for a careful and handy man adapts himself readily to cleaning. As many of the East Indian and warm house orchids are now in a dormant state, these plants should be carefully examined for scale or other insect pests that may have established themselves. In dealing with vandas, ærides and their allied species, it will often be found that, while the leaves may be totally free from insect pests, the axils of the leaves and the stems of the plants are infested. It is not only necessary to dislodge these, but also to carefully remove any dead leaf sheaths lower down the stem.

SCALE is a most troublesome pest, and secretes itself in these difficult positions only to infest the plant the more completely immediately any signs of renewed vitality are apparent. Practically the same remarks will apply to the deciduous dendrobiums, and if these are cleaned before the flower buds plump up, not only can the work be done with less risk of injury, but it will practically ensure the cleanliness of the plants for the next season.

CALANTHES, especially where they have to be grown with other plants, are particularly subjected to attacks from scale, therefore, as fast as the flower spikes are removed, and before they are placed in their resting quarters, it is advisable to carefully examine the pseudo-bulbs. Scale will frequently be found among the roots at the base of the pseudo-bulbs, in the dead bases of the leaves, or even under the outer bulb covering, should this become loose or decayed. As these pests attack the young growth almost immediately they start, the proper cleansing of the pseudo-bulbs is an important item at this season of the year.

PLANTS COMING INTO FLOWER.—At the present season there are many of the early spring and late winter-flowering orchids in various stages of bud development. In the case of odontoglossums that have developed their pseudo-bulbs during the winter months, these will naturally be of a green and sappy nature. It is advisable to harden and ripen such growths as much as possible—in fact, unless this is done, the result will be want of substance as well as of colour in the flowers. It is advisable to place such plants in a position near the glass, where they may receive the full advantage to be obtained from the available light. In the cattleya house the early-flowering species and hybrids will be pushing their flowers forward, and as soon as these can be clearly distinguished in the sheath, the plants must have every assistance that will lead to the satisfactory expansion of the flowers. The flowers of Mexican lælias, especially L. anceps and its varieties, last for a long period when they are placed in a cool, dry atmosphere as soon as the blooms have expanded. H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

POINSETTIAS.—The bulk of our plants have just been removed to a warm corridor, and few plants are better suited for this purpose during the winter months. The bright crimson bracts are very effective when the plants are grown in different heights, upon single stems, and kept in a warm, fairly dry atmosphere, with the roots sufficiently moist to prevent the foliage from flagging. It is remarkable for how long a time they continue effective and retain their foliage, even when the bracts fall. Many of our plants this season developed three distinct sets of bracts in place of the one generally formed, and the effect was good. In many instances the plants will be more forward, and as these are removed from their flowering quarters, with wood not quite matured, place them in a temperature of 50 degs., and give water occasionally to prevent excessive dryness before resting.

PRUNING.—Plants that are required for early flowering, such as allamandas, bougainvilleas, etc., should have that operation performed before they start into growth; but where due attention was given to stopping while growth was in progress, little pruning will be required. Potting is best deferred until growth has fairly started, for at this season root action is very slow. Keep the plants near to the glass, which should be clean.

MEALY BUG.—Use every means to secure the destruction of this pest. In many instances all kinds of produce is expected from under glass, and the removal of plants from one house to another becomes necessary. A week or two at this season can be well spent before active growth commences thoroughly cleaning each plant. Do not spare the plant, whether bush or climber, if difficult to effectually clean, for a fresh start with a clean stock will well repay in view of the incessant warfare that has to be waged against this pest.

TEMPERATURE.—It is unwise at this season to unduly excite plant life, as this means exhausted vitality. For the stove proper it answers best to keep the temperature at the minimum point for a while; a night temperature of 58 to 60 deg. will be ample, rising about 5 deg. in the morning; then slacken the fire for the rest of the day. For the intermediate house or cooler stove 5 deg. lower will be quite safe. The use of the syringe can almost be dispensed with at the present, for with a reduced temperature and no great amount of firing required, moisture will not be so easily dispelled. The evaporating pans may be kept fairly dry if no frosty weather intervenes to necessitate hard firing. Excess of water at the roots at this season is liable to do injury. Allow plants to become moderately dry, and then give sufficient water to moisten the ball through, and use water the same temperature as the house in which the plants are growing.—W. Fyfe, Locking Gardens.

FRUITS UNDER GLASS.

BOTTLING GRAPES.—All bunches of grapes remaining upon the vines should now be cut as soon as possible. They should be cut with long laterals, so that when placed in the bottles they will hang quite clear of them. Before cutting the bunches so fill the bottles with soft water that when placed at a sharp angle the water will reach the necks. Place them in a warm and dry room, a temperature of 50 or 55 deg. being the most suitable. A higher temperature would cause the berries to shrivel quickly, and a lower one would cause damp and decay. Cut out all decaying berries, as one will soon injure its neighbours. Grapes that have ripened well on vines that have not been overcropped keep the best. Muscat of Alexandria, Gros Colmar, and Alicante and Lady Downes are the best grapes for the table at this season.

PRUNING AND CLEANING VINES.—After the grapes are cut the vines should be pruned and the houses thoroughly cleansed. Every portion of the wood, iron, and glass should be subjected to a good scouring, especially if any insect pests have been prevalent. Cleanse the rods by means of a washing with a nicotine preparation, using it at a temperature of 80 deg., and thoroughly soak the bark. After this has been done it will be found an easy matter to pull off the loose bark, under which insects hibernate. Thoroughly wash the walls with hot lime mixed with flowers of sulphur. If a pound packet of size is added to the wash it will adhere to the wall splendidly. Thoroughly clean the border, and top-dress with an approved vine manure, pricking it in with a fork as deep as possible without damaging the roots.

EARLY VINERY.—During very dull or sharp weather do not attempt very hard forcing, but where vines are breaking the temperature should be maintained at about 60 degrees, as, when once started, they must be kept in a progressive state. Damp down as often as is necessary, especially near the pipes and in other dry spots, doing this without causing much vapour. These dry spots in a clean house are often a source of danger from attacks of red-spider.

EARLY PEACH HOUSE.—On bright days well spray the trees. It is not a large amount of moisture that is necessary, but the thorough moistening of the wood. Do not allow the temperature to rise beyond 50 deg., as undue excitement in cold weather may cause the buds to drop. See that the border is not dry near the pipes, and, if necessary, give a good watering, using tepid water.

LATE PEACH HOUSES should be cleaned and the trees pruned and tied. In training avoid crowding the branches, but leave plenty of room for leaf development. When the flowers of the trees in the first house show colour, another house should be started. Avoid, where possible, crowding plants into the peach and other fruit houses. I know that owing to an insufficiency of room this is frequently done, and very often the practice results in the trees or vines being infested, more especially with mealy bug, and gardeners have themselves to blame for allowing infested plants to be brought into fruit houses.

CUCUMBERS.—These plants must be kept in a temperature ranging from 65 to 70 degrees. The floors should be damped several times each day, and the leaves be gently sprayed occasionally, taking advantage of favourable opportunities. Water with weak liquid manure, and lightly top-dress occasionally at this season. Cut fruits as soon as they are of a usable size, and stand them with the stalk end in water in the house where growing. Sutton's Everyday is a good variety, and is just coming into bearing. Carter's Model we were cutting at Christmas, and on New Year's Day. Sow seeds now for a future crop, and put one seed in each pot, which should be of small size.

TOMATOES.—These should be kept on the dry side, and not too warm. Sunrise has been fruiting splendidly, and appears to be an excellent fruit for both early and late uses.—W. A. Cook, Leonardslee Gardens, Horsham, Sussex.

THE KITCHEN GARDEN.

CHICORY is most useful in mixed salads at this season of the year, and in many gardens it might be grown rather more largely than is at present the case. The roots are not difficult to grow, and new growth and well-blanched leaves can be obtained with the aid of a mushroom house or warm cellar. Where chicory is grown the best course is to lift the roots and lay them in trenches with the crowns just above the surface, and then cover them with sufficient leaves to prevent the frost freezing the soil about them. They can then be drawn from and started at any time as required without reference to the condition of the soil. In starting the roots take boxes about twelve inches in depth, and in these pack them rather close together with rather moist soil between them, and at a depth that will bring the crown level with the surface. The boxes containing the roots are then placed in a mushroom house or warm cellar, where new growth soon commences. They may be placed in a shed or glass house, provided light can be excluded and a temperature of 55 or 60 degrees maintained. The leaves should be cut when from six to eight inches long.

CAULIFLOWERS.—Where a supply is required as early as heads can be obtained by the ordinary method of culture, a comparatively small sowing of seed should be made at once of one or more of the varieties of the early forcing type. Sow thinly in pans or shallow boxes, and place them in a structure in which a temperature of about 60 degrees is maintained. When the seedlings begin to make their appearance above the surface place them where they will derive full advantage from the light, and, if convenient, where the temperature will not be much lower than is suggested for the germination of the seeds. There is much risk at this season of the year of losses from damping off, when seedlings of cauliflowers and other brassicas are watered overhead, and therefore, should the soil become dry, stand the boxes or pans in a vessel containing water equal to about two-thirds their depth, and leave until there is evidence of the moisture coming to the surface. When large enough to handle prick off into other boxes, and from these transfer to three-inch pots, putting one in each, and grow in a cool, airy position and gradually harden off.

HOTBEDS are such valuable aids in raising stocks of ornamental and useful plants from seeds, and for the production and rooting of cuttings of various kinds, that the necessary preparations should now be made. Whether early vegetables are in request or not hotbeds will be found most useful at some time or other in assisting various vegetable crops during the preparatory stages, and with crops of carrots, radishes, etc., they are essential. Stable litter and leaves collected in the autumn are the best materials, and when mixed in the proportion of one part litter to two parts of leaves the heat will be steady and long lasting. Both litter and leaves should be well shaken up before they are mixed, and after the mixing they should be turned over every alternate day until the heat has become steady, and the materials are sweetened. Each time the heap is turned over the materials on the outside should be kept towards the centre.

LETTUCES. — Tender lettuces will be in brisk demand from now onward, and arrangements should be made for maintaining a successional supply. Select one of the quick-hearting cabbage varieties of the Tom Thumb type, and sow thinly in boxes, and place them where the seeds will have the assistance of a temperature much the same as advised for cauliflowers. If the young plants are rather crowded transplant in other boxes, putting them about two inches apart. Immediately the leaves begin to touch after transplanting transfer to a hotbed in a suitable state to receive them. A bottom heat of 65 degrees will be sufficient to start them into a vigorous growth. Seedlings not crowded may remain in the seed-boxes until transferred to the hotbed.

FRENCH BEANS.—A sowing should now be made for the purpose of raising a stock of plants that will come into bearing in March. Deep pans, nine or ten inches in diameter, are preferable for sowings thus early. Fill the pans to within half-an-inch of the rim with rich compost, and plant ten seeds in each. If all germinate remove the two weakest plants. The soil should be moist enough to render watering unnecessary until the seedlings are up, and a temperature of about 65 degrees should be maintained.

Lilium Henryi.—One of the finest batches of this lily that I have seen growing was in the garden at West Dean Park, Chichester, where it occupies a position in front of some shrubs on the lawn, in a south-western aspect. At the end of August the plants were still flowering freely at a height of 7 feet. Six years ago the soil was prepared by deep trenching and the addition of peat, leaves, etc., at planting time, and nothing has been done since beyond giving an occasional mulching with leaf-mould. —S. P.

Standard Gooseberry Trees.—The practice of planting standard-trained trees of popular gooseberries does not meet with much favour. Why, it is difficult to say, except it be the question of cost. Fruiting trees with small heads, grafted on the Ribes aureum to obtain the necessary height of 3 to 4 feet, cost about 2s. 6d. each. Carefully managed trees are productive, easy to keep free from insect pests, and to gather the fruit from: and the fruit does not become splashed with soil during heavy rainstorms as in the case of bush trees.—E.

FERN SPORE SOWING.

To those who have any taste at all for the peculiar beauty of ferns, and are capable of exercising a little of that patience and care which are inseparable from success in all of the finer branches of propagative and selective culture, there is no pursuit capable of yielding more satisfactory results in amateur hands than that of sowing fern spores. With the hardy fern varieties which we have in view no heat is required to induce germination, and all the preliminary operations can be effected in a north window, trouble only arising under limited conditions of space when an abundant harvest of good things begin to assert themselves, and demand more and more room for development. Even in the case of only a small garden being available for the overflow, a very good collection can be accommodated therein.

In the very early days of the writer's experiments in this connection, a reference to the register kept from the outset shows that a pinch of spores of a very finely crested Hartstongue yielded about 800 typical plants, not a bad result for a first attempt, and one which acted as a very strong encouragement to continue, and thus led to subsequent results of a very remarkable kind, new and unexpected "strains" arising which have ranked with the most beautiful ferns in the world.

Obviously, to attain such results as these, it is essential to obtain the spores from thoroughbred varieties. Selective culture in plants follows precisely the same lines as selective breeding in animals. Defects are just as likely to be inherited as good points, and no judicious breeder willingly raises stock by means of defective parents. Many ferns are defective in make, the fronds and their parts being irregular or depauperate or inconstant, many, on the other hand, are thoroughbreds, i.e., their fronds are symmetrical, and however varied in character are varied on regular lines. Given such forms we may be fairly sure that the progeny will inherit this regularity and symmetry, while with the others, it is equally to be expected that the irregularities will be transmitted, and the ferns be, as a result, from the present-day point of view, valueless. When, half a century ago, British fern varieties became the "rage," the nurserymen who supplied the market put forward a host of irregular monstrosities, "defectuosums," "irregulares," "depauperatums," "curiosums," etc., etc., which entirely swamped the thoroughbreds, and, as might be expected, gave British ferns such a bad name that the "rage" was a short-lived one, and popular neglect followed.

We mention this as a warning to the would-be fern raiser before we proceed to advise "How it is done," especially as if our advice be followed the crop will be so great that he can very well afford to destroy the ineligible as fast as they appear, and only bring on the very best. Fern spores may really be sown at any time, but the most favourable period is in July or August, so soon as the spore heaps, which are usually seen in dots or lines at the back of adult fern fronds, are brown, and therefore ripe. If a small piece of the frond be detached, and laid back downwards on a sheet of glazed paper, in a few hours a brown snuff-like dust will be shed, and this consists of the spores, and perhaps some of the spore capsules. If a tiny pinch of this deposit be placed on the stage of a microscope it will be seen to consist of thousands of spores, a valuable lesson for the sower, as over thick sowing is a fertile source of failure. Sowing is done in a number of ways; some recommend sowing on a block of peat installed in a saucer of water and covered with a bell-glass, others use a porous brick in the same way. The method, however, which we have found most successful is as follows:

We take a small pot or pan, drain it in the usual way with a few crocks, fill it with ordinary fern compost of leaf-mould and loam, equal parts, and a liberal dash of silver sand. We then top this with crumbs of yellow loam, make the surface even, place a piece of paper on it to prevent washing up, and then pour boiling water on to the paper until it runs out scalding hot at the bottom. This kills possible worms, germs, and other spores, and gives our fern spores a fair field and all the favour possible. When the pot or pan is quite cold we scatter the spores very thinly and evenly over the surface, and cover it with a glass slip. When a number of sowings are in question a very good way is to sow in very small pots bedded in cocoanut fibre in a large square pan, which can be covered with a single pane of glass. These pots can all be scalded at once, fibre and all, but when the sowing is done, each pot should be taken out, and the sowing done some distance away from the others, since spores are very light and float in the air, and hence this precaution is necessary if pure sowings of each variety is desired. A small label with a number should then be inserted in each pot, and the sowing registered for future reference. The pan can then be placed in a well-lighted place out of direct sunshine, and all that is needed is to see that the cocoanut fibre is kept thoroughly moist, no water, however, being poured into the pots themselves.

In a week or two a faint green tinge will pervade the surface of the soil, indicating that the spores have germinated, and in time, a few weeks more, it will be covered with a mass of small green heart-shaped scales. If the sowing has, despite our warning, been too thick, these scales will be small and densely crowded, in which case it is well to prepare a scalded pan of soil, and prick out small clumps of these about the size of a pea, an inch apart, so as to give them room to expand. The next thing will be the appearance of a multitude of tiny fronds amid these scales; then follow others, each larger than the former, and at this stage the experienced eye can usually detect what to encourage and what to repress. The next and successive stages simply consist in separating the youngsters and giving them more and more room, according to their requirements, always weeding out and destroying defective ones, and not forgetting in this transplanting process to number them as per register if any value be attached to pedigree records.

During this process of development, it will probably happen that ferns will appear which have not intentionally been sown, owing to stray spores having fallen on the selected fronds, but more interesting than this may be the appearance of greatly advanced forms, i.e., far better than those sown from, or even very distinct in make. Some most remarkable breaks have occured in this direction, and indeed it is not too much to say that the most beautiful British ferns we possess have thus originated as secondary sports, yet, be it remarked, always from thoroughbred parents. That is a first essential, and we cannot too strongly counsel the sowing only from very good forms, and, having obtained improvements on these, to follow this improvement up by sowing again from the best, since it is in this way that we can raise British ferns higher in the decorative scale.

Chas. T. Druery, V.M.H., F.L.S.

BLOSSOMING OF APPLES.

Mr. Cecil H. Hooper, as already noticed in these columns, has kept a record of the condition of flowering of the different kinds and varieties of fruits at the Wye Agricultural College, Kent, in 1908. This record is published in the December (1908) issue of the "Journal of the Board of Agriculture," and from it we extract the following interesting portion dealing with apples. There is scarcely any need to point out that the comparative earliness or lateness of blossoming of certain varieties may have a very great deal to do with the success or failure of such varieties in certain districts:

The habit of the apple is for the leaves to unfold before the flowers open. Records were taken of ninety-six varieties out of 135 varieties growing in the college plantations; the blossoms were in general abundant and the weather favourable, and without frost.

There seemed to be very little difference in the time of flowering between bush and standard trees of the same variety on cultivated land, nor did the stock appear to influence the date of flowering, whether they were worked on the crab, free, Nonsuch, English broad-leaved paradise, or French narrow-leaved paradise.

One point of interest noticed in the manure trial plots was the late flowering of Wellington apples in a plot without potash. The eight plots received various combinations of artificial manures, and it was observed that Wellingtons on the plot receiving nitrate of soda and superphosphate without potash were notably later in flower than on any of the other plots, including the unmanured; the fruit was less in size and quantity, and the growth also of the trees is less than on other plots.

There does not appear to be any relation between the time of flowering and that of maturing fruit, although some of the early flowering apples, such as Irish Peach, Mank's Codlin, Duchess of Oldenburgh, and Mr. Gladstone come in season early, whilst Court Pendu Plat or the Wiseapple, and most of the cider apples, are the latest to flower, Court Pendu Plat being in season from December to May. Two cooking apples, Golden Noble and Wellington, each commenced to flower on 19th May, were in full bloom on the 27th, and their petals had fallen on 3rd July, but their respective seasons were different, that of Golden Noble being from September to December, that of Wellington from November to March.

The earliest flowering apples were in bloom an average of 16½ days, the second early, 15⅓ days; the mid-season, 14⅔ days; the late flowering, 13¼ days; the latest flowering, 17 days, or an average of 15 days from 83 varieties recorded. The earliest flowering trees took an average of 8 days between commencing to flower and being in full bloom; the second early took 6 days; the mid-season averaged 5 days; the late 5½ days, and the latest also 5½ days. Some varieties, such as Winter Quoining, Hoary Morning, Blenheim Orange, and Loddington, had only a short flowering period of nine to eleven days, whilst of varieties having a long duration of flowering may be mentioned Mank's Codlin, Prince Bismarck, Ribston Pippin, Irish Peach, Cox's Orange Pippin, Bramley's Seedling, Potts's Seedling. Lane's Prince Albert was eighteen or nineteen days in flower, and Graham's Royal Jubilee twenty-one days.

Earliest Flowering Apples.

The earliest varieties in the college plantations in 1908 were: 6th May, Irish Peach (18 days); 9th May, Mank's Codlin (19 days); 10th May, Adam's Pearmain (17 days), and Duchess of Oldenburgh (18 days); 11th May, Prince Bismarck (19 days); 12th May, Pearson's Plate (15 days), Tyler's Kernel (16 days), Gravenstein (16 days), Ribston Pippin (19 days), Charles Ross (19 days), Wagener (10 days), White Transparent (13 days), Mr. Gladstone (16 days), Washington (17 days), and Scarlet Nonpareil (17 days).

Second Early Flowering Apples.

On 13th May, Royal Snow (14 days), Duchess's Favourite (14 days), Byford Wonder (15 days), Warner's King (15 days), Alfriston (15 days), Baumann's Red Winter Reinette (16 days), Boston Russet (17 days), Braddick's Nonpareil (18 days), and Stirling Castle (18 days); 14th May, Shepherd's Fame (10 days), Flower of Kent (11 days), Beauty of Kent (15 days), Calville Malingre (15 days), Christmas Pearmain (16 days), Lord Suffield (17 days), Cox's Orange Pippin (19 days), Saltmarsh's Queen (17 days), and American Mother (21 days); 15th May, King Harry (9 days), Golden Spire (14 days), Hambledon Deux Ans (14 days), Leather-coat (15 days), Beauty of Bath (15 days), Yorkshire Beauty (15 days), Brownlee's Russett (16 days), Worcester Pearmain (16 days), Peasgood's Nonsuch (16 days), Okera (16 days), and New Hawthornden (17 days).

Mid-season Flowering Apples.

On 16th May, Twenty Ounce commenced to flower, and continued in bloom 12 days, Scott's Winter (13 days), Roundway Nonsuch, Roundway Magnum Bonum, D'Arcy Spice (15 days), Fearn's Pippin (16 days), Lady Sudeley (16 days), Bramley's Seedling (18 days), Potts's Seedling (18 days), Royal Late (18 days), and Lane's Prince Albert (18 days); 7th May, Egremont Russet, Allen's Everlasting (12 days), and Summer Pippin (15 days); 18th May, Winter Quoining (9 days), Hoary Morning (10 days), Colonel Vaughan, Mère de Ménage (13 days), Sturmer Pippin (13 days), Norfolk Wonder (13 days), Lady Henniker (14 days), Betty Geeson (14 days), King of the Pippins (15 days), Gascoyne's Scarlet (16 days), Seaton House (16 days), Brabant Bellefleur (16 days), Gloria Mundi (15 days), Belle de Pontoise (16 days), Cat's-head (16 days), Allington Pippin (16 days), and Vicar of Beighton.

Late Flowering Apples.

On 19th May, Hambling's Seedling, Lord Derby (13 days), Ecklinville (14 days), Striped Beefing, Calville Rouge (cider), Golden Noble (16 days), Wellington (16 days); 20th May, Foster's Seedling (11 days), Slack my Girdle (cider) (10 days), Dutch Mignonne, London Pippin, Cornish Gilliflower (12 days), and the Sandringham (16 days); 21st May, Blenheim Orange (11 days), Loddington (11 days).

Latest Apples.

23rd May, Graham's Royal Jubilee (21 days), and Jersey Chisel (cider); 26th May, Cherry Pearmain (cider) (16 days), and Foxwhelp (cider); 27th May, Medlar commenced to flower—full bloom 3rd June, petals fallen 15th June (20 days); 28th May, Broad-leaved Norman (cider) (16 days); 30th May, Court Pendu Plat (14 days); 3rd June, Argile Gris (cider).

Mr. F. Ivo Neame, of Faversham, has sent me a record for 1907 and 1908 of the opening, full blossom, and fall of petals of some 22 apples and 7 pears, taken at his farms at Selling and Chilham, which corresponds fairly closely with my own record at Wye.

Mr. Frederick Chittenden, however, has sent particulars of the record of blossoming, taken at the Royal Horticultural Society's gardens at Wisley, Surrey, in which he points out some instances in which the order of flowering at Wisley differs from mine, showing that observations should be taken in different localities and for several years to get greater exactitude.

Mr. Edward A. Bunyard, who kindly sent me notes on the first flowers of some 170 varieties taken this year at Maidstone, remarked: "It is curious to notice the short duration of blossom this year, from earliest to latest only about fifteen days.

Period of Blossoming in United States.

A bulletin issued this year by the New York Experiment Station on "The Relation of the Weather to the Setting of Fruit," gives the average duration, according to six years' record, in that State, as about 9 days for apples, while five years' records show pears to be 7 days in flower; peaches, 8 days; plums, 7 days; cherries, 7 days; and grapes, 10 days. The number of trees on which the observations were made is given in each case, and varies from three to six. The first varieties of apples began to flower on 10th May, the last on 20th May. The shortest length of time for any apple to be in flower is six days, and the longest twelve days. Thus the apple trees in this State appear to take but nine days, to do what takes the apples here fifteen days to accomplish. No correlation was observed between the times of blooming and fruiting, but much stress is laid on the importance of cross-fertilisation, and the planting together of varieties that bloom simultaneously is recommended.

The order of flowering of different varieties in New York State is in general similar to that in England. The Gravenstein, Duchess of Oldenburgh, Twenty Ounce, Wagener, Washington, Gladstone, Bismarck, and Beauty of Bath are among the early bloomers, whilst the later ones include Ribston, King of the Pippins, Cox's Orange, and Lane's Prince Albert.

My thanks, writes Mr. Hooper, are due to the Principal of the South Eastern Agricultural College, Professor M. J. R. Dunstan, M.A., for the use of the College plantations for observation, and to Mr. Seymour Deadman, Instructor in Fruit-growing, for his assistance and information, particularly as to varieties; also to those gentlemen who have kindly allowed me to compare their records of time of blossoming with my own.

WHITE JAPANESE CHRYSANTHEMUMS.

Although we have an immense number of desirable white-flowered chrysanthemums suitable for the ordinary forms of decoration, one cannot but realise how scarce are the best of exhibition varieties becoming. There appears to be a dearth of this type of flower, and nothing since the introduction of Mrs. A. T. Miller have we seen that is likely to become prominent and retain a high position. Anyone who can introduce a variety as good as Mrs. A. T. Miller, which is not quite of the quality it was at one time owing to its constitution becoming weaker, will, I am sure, reap a rich reward. Since the introduction of Mrs. A. T. Miller we have had nothing of a similar character, although, no doubt, introducers claim high favours for certain varieties. If we examine the reports of shows we quickly find a paucity of white varieties. For instance, the premier collection in the vase class at the November show of the National Chrysanthemum Society for twelve varieties contained but two white varieties, namely, Edith Smith and Maud Jefferies, and of the eighteen varieties named in the report of the thirty-six class at the same show but one white variety, Mrs. Norman Davis, is given. In the large class at Edinburgh for fifteen varieties, quite at the end of the season, we find there but two whites, Marquis V. Venosta and Miss R. Stoop. In the Scottish cup class for eight varieties but one was staged, Mrs. A. T. Miller. It was the same at all other shows; there is a paucity of white-flowered varieties, but plenty of yellows. At Edinburgh there were no fewer than five in the premier collection of fifteen, and four in the first prize collection of twelve vases at the N.C.S. exhibition.

Varieties of somewhat recent introduction as whites are Formality, which I regard as being much too small for present-day requirements, but a promising variety for decoration; F. W. Lever is promising, if deeply built enough; North Pole has little promise of value; Mrs. J. W. Cole is a sport from a variety now exhausted. Miss Faith Moore, too small. The newer variety, Mrs. Norman Davis, has not made the headway amongst exhibitors that was expected. Somehow the blooms do not build up so shapely or full as is desirable in the finest of exhibition specimens. E. MOLYNEUX.

"CHRYSANTHEMUMS AND HOW TO GROW THEM FOR EXHIBITION," by J. B. Wroe. Fifth Edition, revised to January, 1908, and including the new varieties.—Full details on timing and stopping for Northern, Southern, and Midland growers, selections of the best varieties, illustrated instructions on taking the buds, cuttings, staging, etc. Prices 1s. net, by post 1s. 2d.; cloth, 1s. 6d., by post 1s. 8d., from Wm. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

Royal Dublin Society.

In accordance with the usual custom, the Royal Dublin Society arranged a short winter course of lectures adapted to the requirements of an audience of juveniles. The course was inaugurated by the first of two lectures by Mr. F. W. Moore, V.M.H., keeper of the Glasnevin Botanic Gardens, on "Plant Life." This lecture was devoted to "Plants which like Wet Feet," and while strictly scientific in treatment, proved immensely interesting to the large number of juveniles who had assembled in the lecture theatre of Leinster House.

In his opening remarks, Mr. Moore directed attention to the necessity of water in the life of plants, and described its functions. When plants were supplied with water they were not being given food, but only the material out of which they could make their food. It should also be borne in mind that there was not in water all that was necessary for the life of plants. They required certain mineral food, such as magnesia and potash, and these as well as other substances such as carbon were necessary to continue the chain of their existence. The mineral substances, even though they might be required in small quantities, were just as much a necessity to the plant as carbon, though the latter might be almost half its weight. These mineral constituents were supplied in solution by water, and plants derived them from the soil by means of their roots. The water was distributed through the plant by means of a delicately elaborate system, which the lecturer explained by means of lantern slides. As showing the amount of water which entered into the composition of plants it was mentioned that the apple contained 85 per cent., the peach and the melon 90 per cent., and the potato 75 per cent. The process of ripening, generally speaking, meant the process by means of which the superfluous water was driven off without disturbing the tissue of the plant. For instance, in haymaking 65 per cent. of the water contained in meadow hay was driven off. Proceeding to deal more in detail with his subject, Mr. Moore explained the adaptations which enabled water lilies and other such plants to live in water, and the distinctions to be drawn between plants living in running water as distinguished from still water. A contrast was also made between a giant water plant, such as the lotus, as found in Egypt, India, and China, and the small water lily as found in this country. Other interesting points in the lecture were those relating to waterside and bog plants, and the changes which were brought about in them as summer passed into winter.

Windsor Rose Society.

The Mayor of Windsor presided over the annual meeting of this society, which was held in the Guildhall Council Chamber. There was a large attendance of members, and the report and balance-sheet presented were of a highly satisfactory character.

The report stated that the society might be heartily congratulated upon the progress made during the year, and upon the remarkable success of the annual exhibition, which was held on the slopes of Windsor Castle. There was a magnificent display of roses, the members attended in large numbers, and the general public were so strongly represented as to show the great interest taken in the society and its work. The Hon. Treasurer, in presenting the financial statement, said there was a substantial balance in hand. The Mayor of Windsor, in moving the adoption of the report, spoke of its successful character and of the splendid work that had been accomplished by the society. The motion having been duly seconded, was unanimously adopted.

The Marquis of Normanby was re-elected president; Mr. C. H. Burt, hon. secretary; the Rev. S. K. Tahourdin, hon. treasurer; and Mr. Street, hon. auditor.

The next annual exhibition was fixed for Saturday, June 26.

Reading Gardeners' Association.

The recent fortnightly meeting of the year was held in the Abbey Hall, when, owing doubtless to the inclemency of the weather, the attendance was not so large. Mr. T. Tunbridge, chairman, presided, and the nomination of officers for 1909, the election to take place at the annual meeting on January 11, was first proceeded with.

The subject for the evening was "Strawberries in Pots," the lecturer being Mr. Durbidge, of the Gardens, Mapledurham House, who, in a brief but very practical paper, gave some particularly valuable information respecting the propagation, feeding, and subsequent fruiting of the "Queen" of spring fruits. Mr. Durbidge also named the varieties he had by experience found best suited for culture in pots, and concluded his paper with a few useful hints with reference to the packing of strawberries when, as was often the case, it was required to forward them per rail or parcel post.

A highly instructive debate followed, as may be gathered from the number taking part in the discussion, which included Messrs. Alderman F. B. Parfitt (president), T. Tunbridge, T. Neve, Hinton, W. Townsend, H. C. Loader, L. Castle (hon. secretary), H. Goodyer, Winterbourne, C. Woolford, E. J. Dore, Wilson, Reeves, F. Townsend, Alexander, Judd, Selman.

APPLE SALES.

"H," on p. 968, 1908, writes, I think, without experience of apple sales, but from hearsay. I do say that overstocked markets at the end of September and October are the cause of low prices. I do not mean they are overstocked by English fruit, but by that from other countries. The middle of last November I had a conversation with one of the largest fruit merchants in the south of England, one who handles yearly many tons of apples for a large shipping business. When offering him a big batch of Bramley's Seedling apple, he said, "I do not wish to see another English apple this year; just look at this consignment I have received from a new apple centre." Washington State, I think he said. My reply was: "Yes, they have a fine appearance, are beautifully coloured and graded, but what of the flavour?" "Oh, quite good enough for my purpose," he said. "How can you compare your Bramley's with these?"

Eventually he offered me 5s. per bushel for my lot! Now, what would "H." say to such an offer, and what would be his remedy? It will be interesting to learn. He knows that foreign apples will continue to arrive from one place or another until next June, and that the price of English fruit will not increase. "H." cannot be conversant with apple sales, or he would know that the average quotation per bushel in Covent Garden is 6s. for Annie Elizabeth, and 5s. 6d. for Bramley's.

If "H." had a little experience of growing and selling I venture to say he would not write so glibly about the sales. If the British public, who consume apples, knew, or cared, more about the quality than they appear to do now, and were less carried away by a bright exterior, there might still be a fair chance for the ordinary grower. I do not say there are more apples produced in this country at the end of September than can be consumed, but I do say we cannot compete with foreigners until we get the British public to lend us a helping hand.

E. M.

NEW AND OLD PLANT HOUSES.

The early hours of December 29, 1908, will long be remembered by gardeners from their trying experiences with the various hot-houses under their charge. On such a morning the outdoor gardener scored points; that is, the single-handed man, who has no "glass."

A very practical lesson was taught us of the superiority of new and up-to-date hot-houses to old houses. Drip is the cause of much mischief in old houses, and it occurs with snow as well as with rain, when the panes of glass in old houses do not fit. On the morning of December 29 the young man in charge of the fires looked like a defeated hero, for he had heroically tried to keep up the temperatures, but was beaten, especially in the old houses.

Our houses vary in age from nearly sixty years to sixteen months, and I never saw such a sight in my life as in one of the old houses, the principal sufferers, amongst other plants less tender, being a large batch of cinerarias. The very thin snow as it fell was so fine that, with the aid of a fearful wind, it found its way into the house by way of the laps of the glass, and the plants were weighted down with it. Some of the largest leaves were broken off. There was no frost in the house, but I had the plants quickly taken to a dark shed, where they remained until the snow had melted, and they do not seem much the worse for their covering. In some parts of the old houses there were large drifts of snow, which had insidiously crept in at the large laps. We have eight houses devoted to orchids only, and one of these is comparatively old, having been erected in 1881. This is filled with cattleyas, and on Monday, December 28, owing to the low temperature, I instructed a man, who was cleaning plants in the house, to stop up the crevices where the lights did not fit with strips of old shading material, and by taking this precaution very little snow found its way inside. We have just twenty hot-houses, of which only four are old, as we have done much rebuilding within recent years.

This experience brings into relief the futility of expecting good results from tumble-down, rotten old plant houses, as besides admitting cold winds and snow, they let in the terrible fogs. It is no use closing an old hothouse to keep the deadly enemy, fog, out, when it can enter at so many places. Of course, all new houses will become old in process of time, but when commencing to fall to pieces, as it were, they should be renewed. It will be found that a great saving is effected in fuel with a hot-house that is quite sound. Repairing old greenhouses is the most unsatisfactory work a carpenter or joiner can undertake.

Cheshire. W. M.

Heliotrope Mdme. de Bussey.—Those who are seeking a desirable heliotrope for the flower garden could not do better than procure this dwarf-growing variety, which produces enormous flower trusses of an exceptionally attractive colour and delicious perfume. Growing as standards, with the pots plunged in grass, in a mass, with sufficient space between for each plant to stand alone, it produces a fine effect in the garden, especially if backed up by greenery of some kind.—S.

Plants of Humea elegans that are being wintered with a view to employing them in the flower garden next summer will require close attention in watering throughout the dullest months of winter. A mistake is often made by unduly inciting growth in winter by very high temperatures, whereas a moderately warm greenhouse, with a maximum temperature of 55 degrees, will meet all their requirements, and provided the water supply is carefully regulated, they will turn out strong and well-rooted, capable of being shifted on into larger pots as soon as the days lengthen in spring.—THOMAS SMITH, Walmsgate Gardens, Louth.

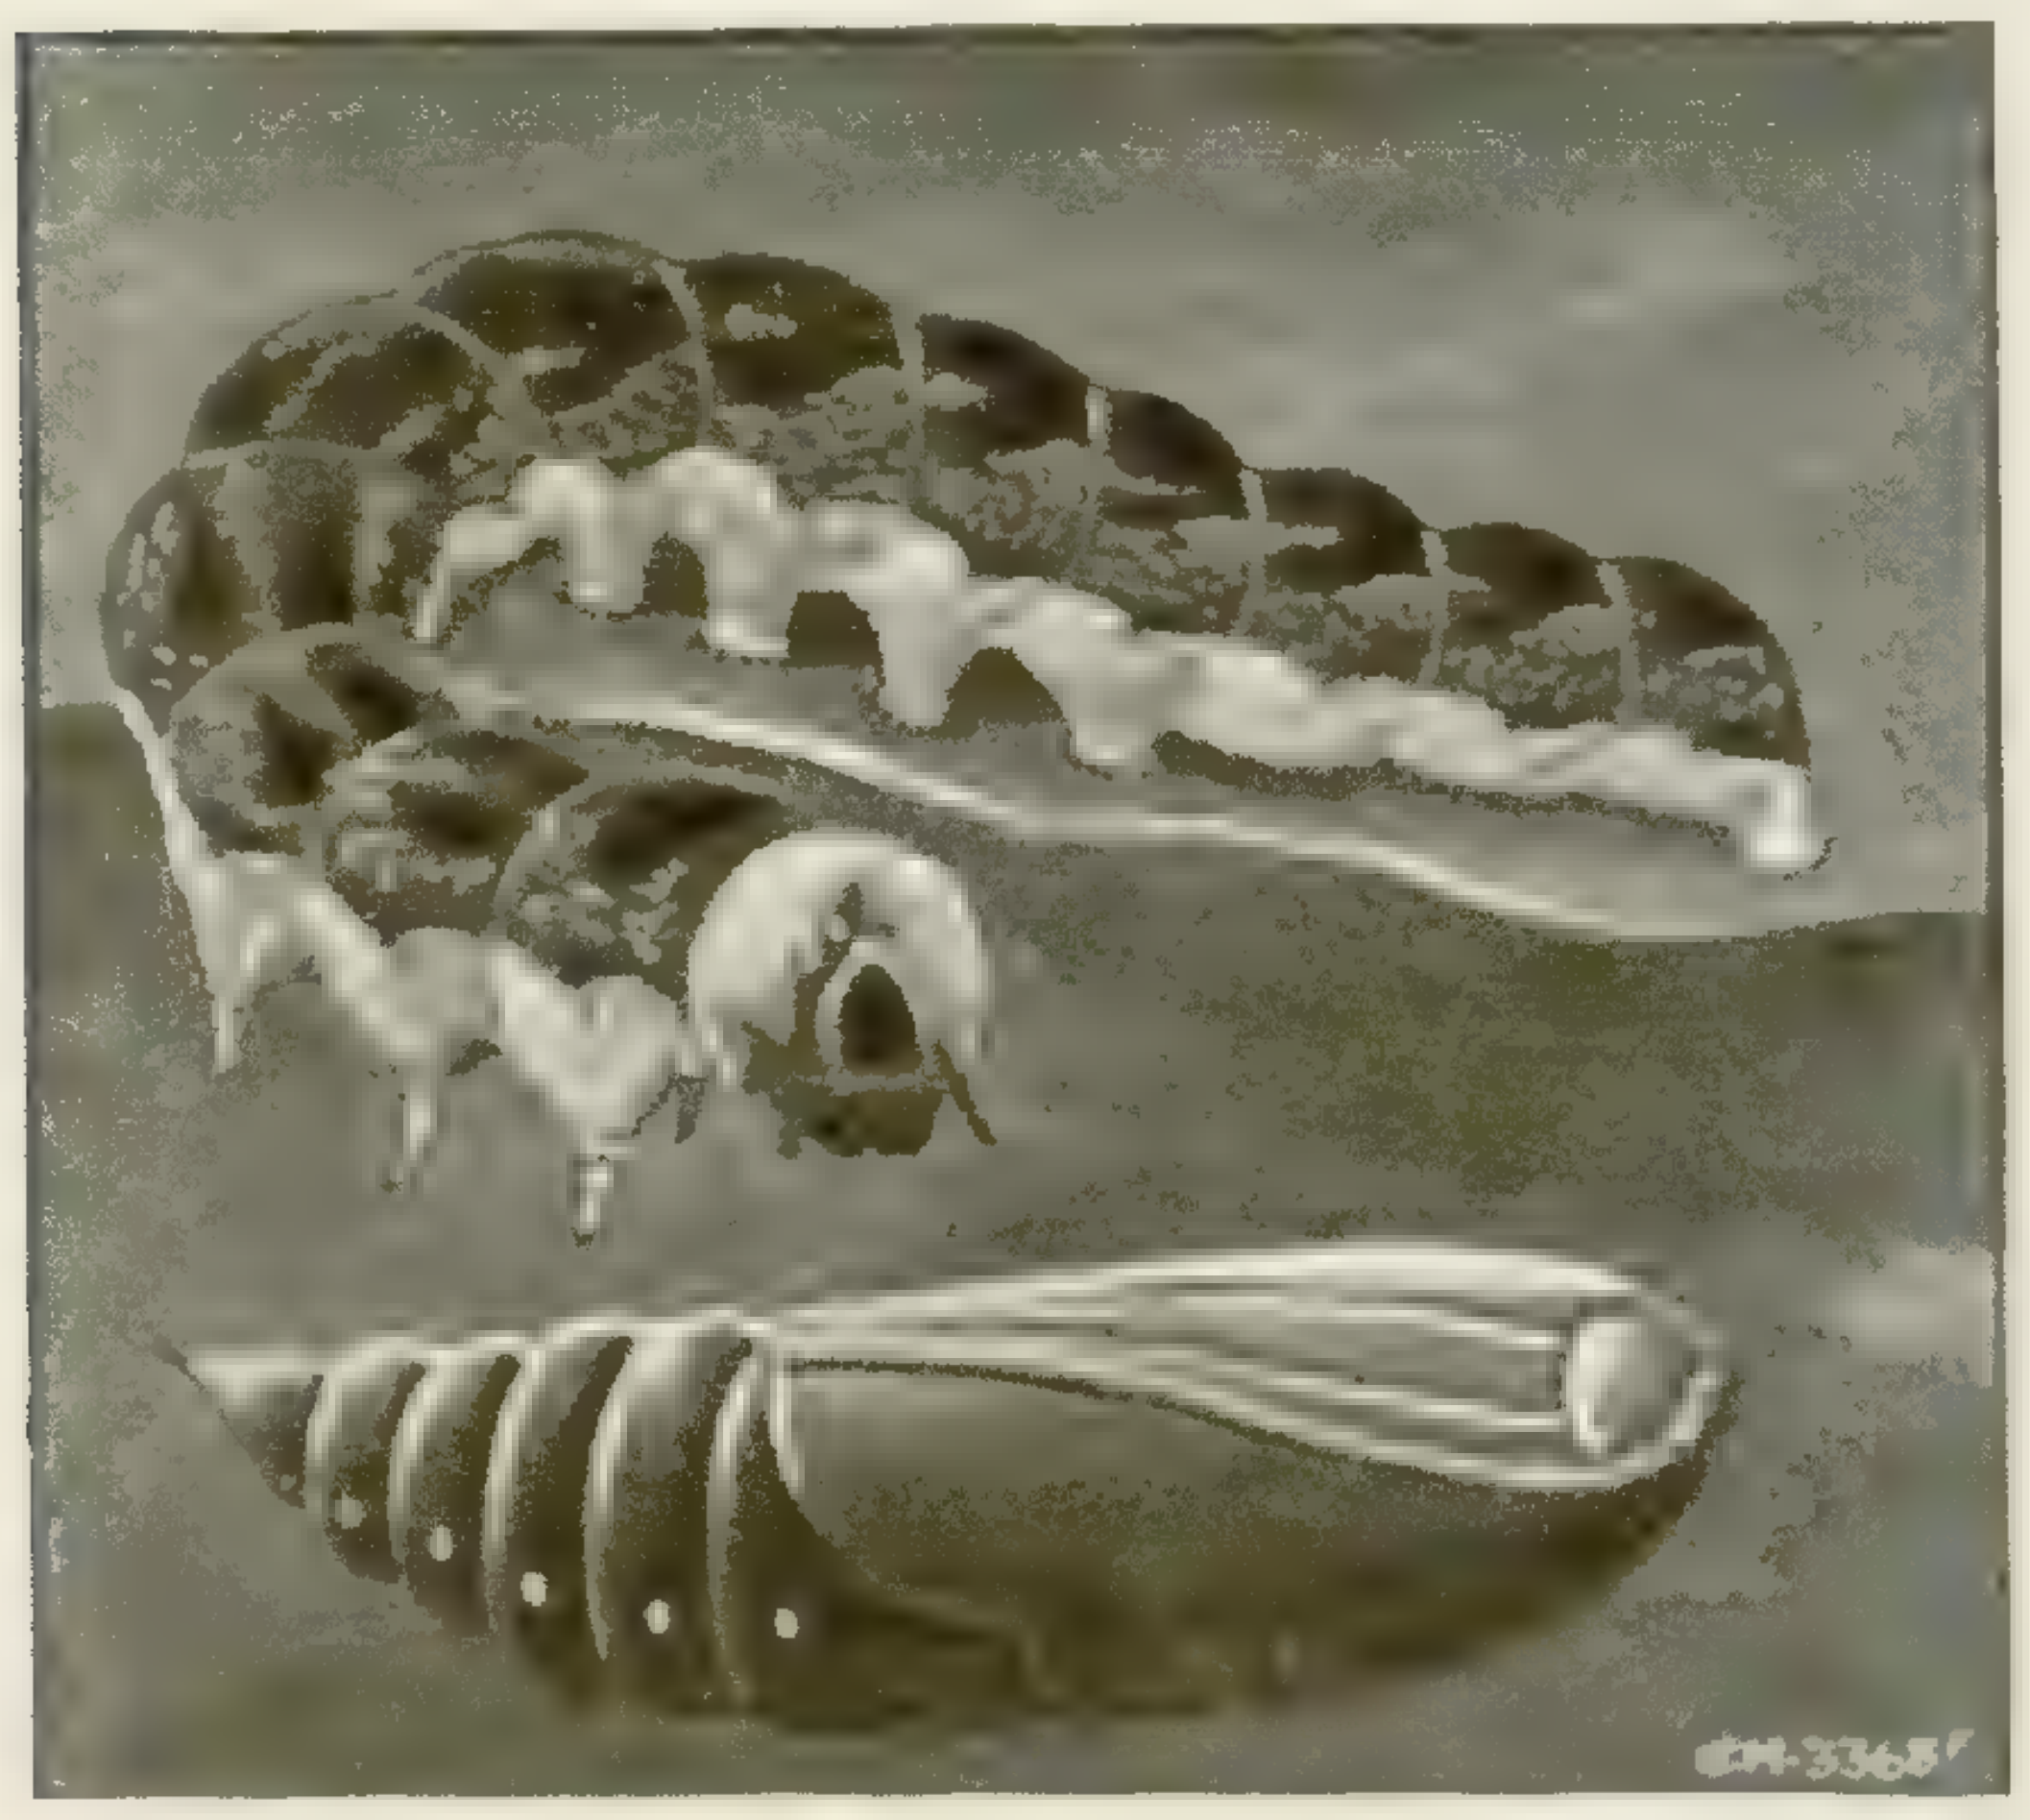
ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

BEAUTY OF WILTS APPLE.—A. S., Guildford: We submitted the specimens to a well known authority, who writes us that the variety is Round Winter Nonsuch, sometimes known as Beauty of Wilts. Mr. T. Smith, Coombe House Gardens, Westbury-on-Trym, writes: "Re Beauty of Wilts apple, 'Scott's Orchardist' has the following: Beauty of Wilts, Dredge's (Harvey's) Pippin. Fruit medium sized; roundish Skin, yellow on the shaded side, but washed with fine red and marked with crimson dots on the sunny side; flesh firm, crisp, juicy, and richly flavoured; a first-rate fruit, and the tree attains the middle size, is healthy, and a prolific bearer." Turning to Dr. Hogg's "Fruit Manual," we find "Dredge's Beauty of Wilts" referred to Harvey's Pippin, and under the latter we find a description very closely like the one Mr. T. Smith has sent, as above, but it differs a little, and points out that the variety is "an excellent apple, either for culinary purposes or dessert use; it is in season from December to February. The tree is a free grower, and an excellent bearer; it attains above the middle size, and may be grown either as an open dwarf, or an espalier, when grafted on the paradise stock."



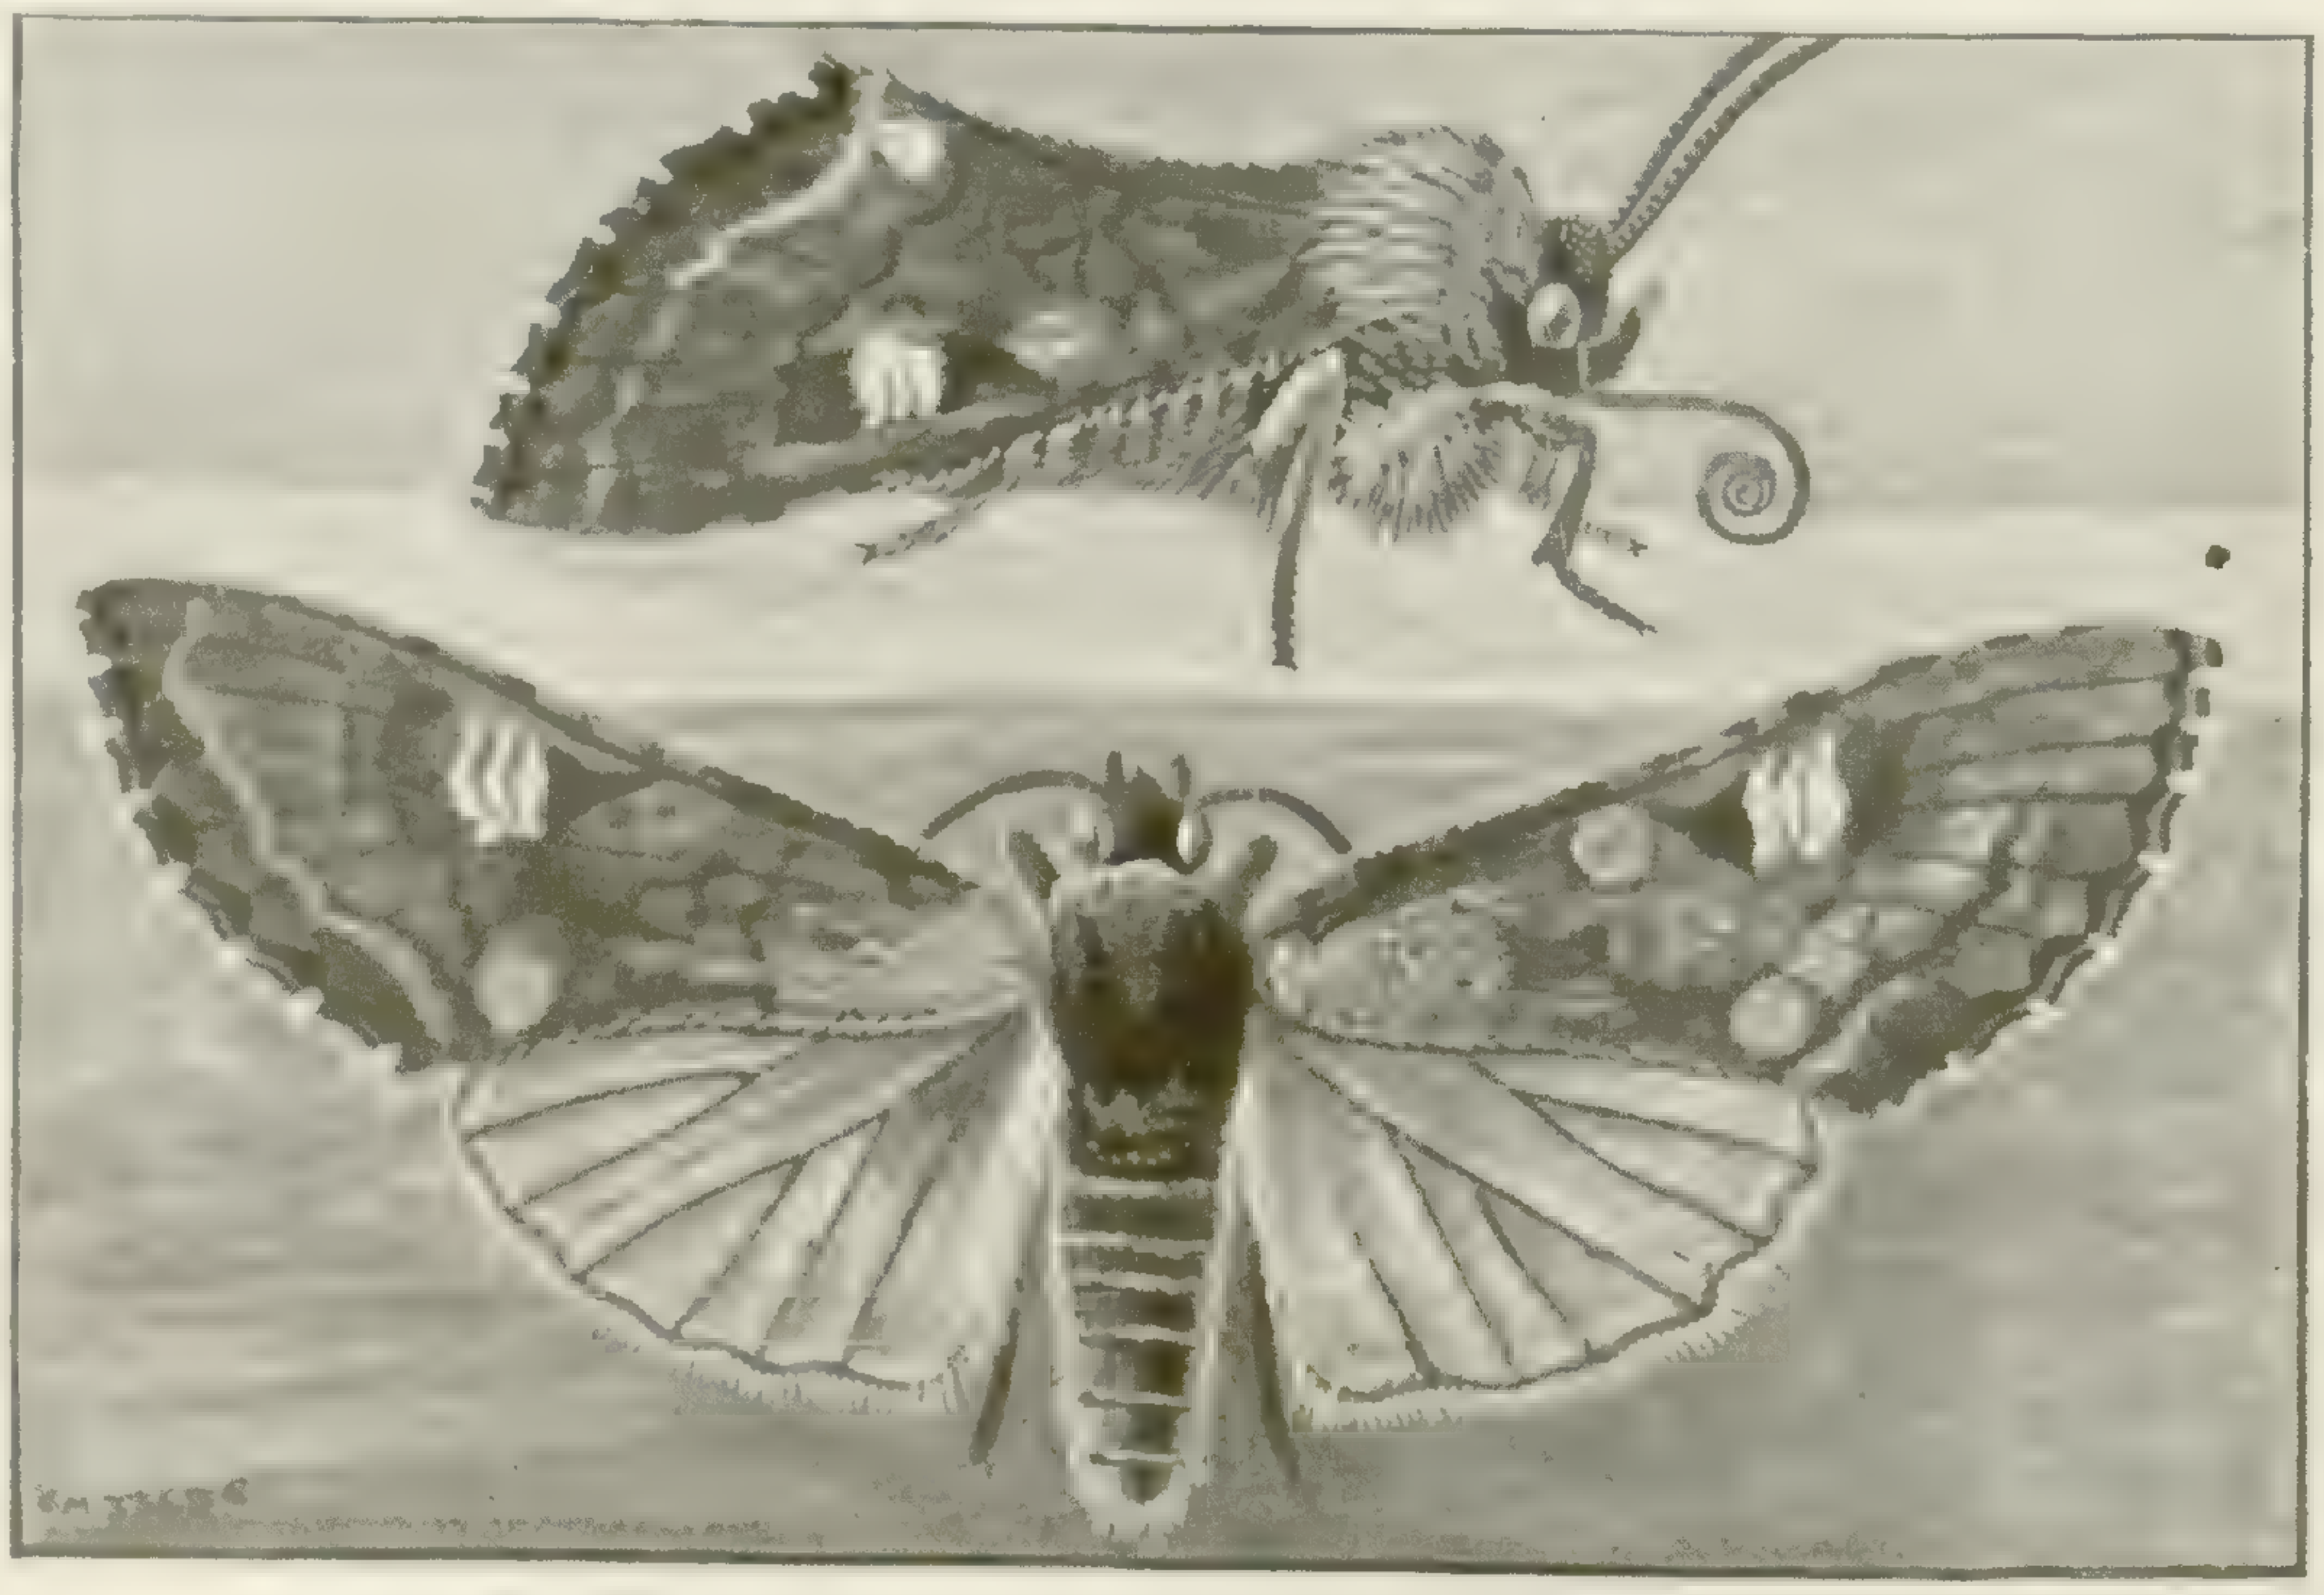
CATERPILLAR AND CHRYSALIS OF THE CABBAGE MOTH.

HARDY PERENNIALS.—M. E., Hertford: Tree lupins, pentstemons, carnations, and Lilium candidum are certainly all hardy perennials, but they are not all hardy herbaceous perennials; indeed, Lilium candidum is the only one that properly answers to the latter description.

BEGONIAS FOR THE CONSERVATORY.—E. C. J., Cardiff: It is by no means necessary to obtain tubers of named varieties of begonias, unless one desires to make a speciality of these flowers. The best strains of seeds now give such fine varieties of the tuberous section that, in most gardens, the named varieties are not essential. Good flowering plants may be obtained in three or four months from seed sown in February, but the amateur with few conveniences should purchase corms mixed, or in distinct colours, raised from seed in the year previous, as they are inexpensive, and will save much trouble. The most suitable compost is one consisting of mellow fibrous loam, and small proportions of powdery manure and silver sand. Start the corms with little artificial heat, and preferably in a pit where they can have a position near the glass and enjoy liberal atmospheric humidity and a free circulation of air. The fibrous-rooted or shrubby begonias are useful for giving colour to the stove and intermediate house from October to April. The tops of the shoots strike readily with the assistance of a brisk temperature and sandy soil, and the best month in which to propagate a stock is March. Single plants in five or six-inch pots are the most useful. Ornamental-leaved begonias are readily propagated by means of their leaves during the summer. They require an intermediate temperature, liberal supplies of water, and a moderately light position, without exposure to the direct rays of the sun.

SINGLE CHRYSANTHEMUMS.—E. M. A., Formby: Many thanks for your kindly letter. Cuttings of single chrysanthemums should be taken any time during the present month. The plants may be treated pretty much on the same lines as Japanese varieties so far as potting, etc., is concerned, but they will not need such heavy feeding. The plants should have their growing points pinched out several times during the summer, but should be allowed to extend from June or July onwards. Some amount of disbudding will be necessary for show purposes, as one flower per stem will then be sufficient unless the blooms have to be shown in sprays. Excluding the very newest varieties, as these have not all been sufficiently proven, a good dozen of single chrysanthemums for exhibition would consist of Annie Farina, Edith Pagram, Mrs. J. F. McLeod, Bronze Pagram, Kate Williams, Eureka, Earlswood Glory, Mrs. E. Cannell, Elsie Neville, Crown Jewel, Pretoria, Miss Tackey Bird, Sylvia, and Grace. Mr. Crane's articles on "Late Single Chrysanthemums," now appearing, will be of material assistance to you.

CABBAGE MOTH.—N. R. T., Chesham: It is not at all an easy matter to identify a chrysalis, but our opinion that the one sent represented the cabbage moth was confirmed by your subsequent letter, in which the moths that attacked your cabbage crops last year, were fairly well described. This moth (Mamestra brassicæ) lays its eggs upon cabbages and similar crops about May, and the caterpillars appear in about a fortnight, and are ready for pupation about a month later. Two broods appear during the season, hence the greater need for reducing the pest in every possible way. The caterpillars are dull greenish-grey, with a yellowish undersurface, and their general features, as well as those of the chrysalis, are shown in the present illustration, which represents them larger than life size. The moths, also represented larger than life size, fly during evening and night, though sometimes seen by day, and are therefore not so easily detected as the day-flying cabbage butterfly. Moreover, the caterpillars hide beneath the leaves during the daytime, and quickly eat into the heart of a cabbage, rendering the latter uneatable and causing it to soon turn rotten. The chrysalids of the late brood pass the winter in the soil beneath the crops they have infested, though they are not seldom found in the rubbish heap, having been carted there during a general clear up of the infested plot. This points to the necessity of regularly burning or quick-liming the material in the rubbish corner. Hand-picking at the time of the infestation—May, June, and July—is a matter of first importance, and a keen-sighted boy will soon rid a plot of these unpleasant and unwelcome guests. At present the soil should be examined for the chrysalis, and these, as found, may be burned or thrown into the chicken run, where they will soon be made short work of.



CABBAGE MOTH.

NAMES OF PLANTS.

C. G. J., Homersham.—Acacia dealbata.

T. M., Merthyr.—1, Cratægus Lelandi; 2, Exacum affine; 3, Moschosma riparia.

F. B. J., Winchester.—1, Cryptomeria elegans; 2, Thuia dolobrata; 3, Eucalyptus globulus.

F. F., Derby.—1, Euphorbia splendens; 2, Opuntia ficus-indica; 3, Ficus radicans variegata.

M. D. E., Dulwich.—1, Woodwardia radicans; 2, Davallia bullata; 3, D. pentaphylla; 4, Eriostemon buxifolium; 5, Ophiopogon Jaburan.

NAMES OF FRUITS.

H. M. S., London.—Ribston Pippin.

W. B., Horley.—Grange's Pearmain.

Messrs. Dickson and Robinson's Annual Dinner.—For the thirteenth consecutive year has just taken place the annual dinner given to the employees by the firm of Messrs. Dickson and Robinson, the King's seedsmen, of Manchester. Held at the Victoria Hotel in that city, and presided over, as it has been from the first, by the firm's senior partner, Mr. Robinson, the evening proved a greater success than any one of those past. Pleasant exchanges of the markedly good feeling between the firm and its staff were embodied in the toasts. A pleasing little digression in the programme made, to all present, the evening of special interest. The recent marriage of Mr. W. P. Robinson gave opportunity to the staff to give practical expression to their good wishes for his future happiness, and consolidate even more the ever-existing good feeling. This expression took the form of a handsome clock suitably inscribed. Mr. Anderson made the presentation, and was supported by Mr. Ward.

NOTES OF OBSERVATION.

Coleus thyrsoideus supplies a colour among indoor winter-flowering plants that is far from being common. The plants are voracious feeders, and unless grown in small pots they are inclined to grow rather coarse. Confined to 4¾in. pots, and grown in a cool greenhouse until the approach of winter, the resulting plants are dwarf and stocky. Weak liquid manure will prove beneficial if applied previous to flowering. As the majority of spring-blooming plants produce light-coloured flowers, we can, by the grouping of this coleus, add brightness and variety, features which at this season are doubly welcome.—THOMAS SMITH, Walmsgate Gardens, Louth.

Flowers in Bloom.—Notwithstanding the severe frost here, 24 degrees in the American Garden (19 degrees in the screen), Erica lusitanica, Chimonanthus fragrans, and Jasminum nudiflorum are flowering freely, and present a bright appearance. The hellebores and Galanthus Elwesi are just opening their flowers. With reference to this snowdrop it may be stated that, when birds are destructive, it is a good plan to use some black cotton, twisted about on small green twigs. This will frighten them away, and will not appear unsightly. Erica carnea does not appear to have taken any harm from the frost, as the plants are as smart as ever. —W. A. COOK, Leonardslee Gardens.

Pelargonium Paul Crampel as a Standard.—Those who require standard pelargoniums in pots for placing in suitable positions on terraces and lawns, or other desirable situations in summer, should grow this, the brightest of all summer-flowering varieties. Plants raised from stout cuttings grown on vigorously soon reach the height required, three feet to four feet for the taller specimens. By repeated pinching of the points as fast as a little growth is made, the foundation of good heads is soon made, and the plants can afterwards be grown on as desired. As a free-flowering variety this pelargonium has few equals, and certainly no superior, when we consider its vigorous growth. In the gardens at West Dean Park last summer I saw some charming standards of this variety, arranged on the grass with a background of evergreens, and the great masses of flower trusses produced a brilliant effect.—S.

Lonicera fragrantissima. — This is one of the earliest honeysuckles to blossom, its flowers appearing with the earliest days of the year when the weather is favourable. It was introduced from China by Robert Fortune over half-a-century ago, and one of the first plants introduced to this country is recorded as being in the Horticultural Society's garden, growing against a wall, about, or previous to, 1850. This, however, was not the first plant to blossom in the country, for, according to Lindley and Paxton, in their "Flower Garden," vol. iii, p. 75, Fig. 268, it blossomed for the first time in the garden of the Marquis of Salisbury at Hatfield, in January, 1852. When mature it attains a height of 5ft. or 6ft., with a wide spread. The leaves are semi-evergreen, being retained until well on into spring. The flowers are borne, usually in pairs, from the leaf axils; they are pure white, and very fragrant. A second species, L. Standishi, also flowers about the same time. It likewise is a Chinese species, and confusion often exists between the two plants. The latter is the better-known shrub, and differs by having larger hairy leaves, which are not retained after autumn, and by its stiffer habit and cream-coloured flowers. The points of resemblance are, they bloom at the same time, and the flowers of both are fragrant. Both species thrive in loamy soil, and are suitable for outdoor borders or for placing in pots to blossom in the greenhouse for the sake of their fragrance. L. Standishi bears ornamental fruit. When ripe it is scarlet.—W. D.

OBITUARY.

MR. GEORGE FIELD MORRIS, F.S.I.

We regret to have to announce the death of Mr. George Field Morris, F.S.I. (late senior partner of the well-known firm of Messrs. Protheroe and Morris), which took place at his residence, Madeira, Cambridge Park, Wanstead, early on Saturday last.

The deceased gentleman was born on September 2, 1831, and educated at Forest Place Academy, Leytonstone. His father, Mr. Thomas Morris, was one of the two founders of the firm of Messrs. Protheroe and Morris, who commenced business as horticultural auctioneers and nurserymen about the year 1830 at Highbury, but it was in 1840, when the American nurseries at Leytonstone were acquired that the modern development of the firm commenced. To our readers their name is doubtless familiar in connection with the sales of orchids, lilies, and bulbs of every description, which take place periodically at their headquarters, 67 and 68, Cheapside. The late Mr. Morris, at the age of fourteen, entered the nursery business, and early made himself acquainted with those details of horticulture which stood him in good stead in after years.

As an auctioneer, he conducted his first sale in 1860, and opened a branch at Leytonstone in 1870. Four years later, in conjunction with the late Mr. W. H. Protheroe, he established a city office at 98, Gracechurch Street, and subsequently at the present offices in Cheapside. His was a well-known figure at the Mart and Garraways, while the firm's special horticultural sales took him into all parts of the country; in addition to which he enjoyed a considerable practice in arbitrations and railway claims.

After being a member of the firm for fifty-eight years, he retired in 1903 to enjoy a well-earned leisure in the cultivation of the beautiful grounds of Madeira, his private residence at Wanstead. The late Mr. Morris was an excellent musician, and another of his hobbies was painting in water colours—a capital little landscape being completed by him as recently as last month. Golf, cycling, and long walks were his favourite recreations.

He was twice married, and leaves a son and daughter, the former, Mr. Harold George Morris, having been a partner in the firm since 1889. Mr. Morris had only been ill for a short time, the actual cause of death being heart failure. His remains were interred in the City of London Cemetery, Manor Park, on Tuesday.

THE POISONS AND PHARMACY ACT, 1908.

The Traders in Poisonous Compounds for Trade Purposes Protection Society was formed in 1900 in consequence of prosecutions which had taken place of tradesmen (nurserymen, seedsmen, and ironmongers), for having sold or kept open shops for the sale of insecticides, weed killers, and sheep dips, containing a poison, and notably the cases of the Pharmaceutical Society v. White, and the Pharmaceutical Society v. Wrench. The writer, who was the promoter of the society, was appointed treasurer, a position he still fills, and Mr. T. G. Dobbs, of 14, Sansome Street, Worcester, was appointed and continues to act as secretary and solicitor. Offices were taken at 5, Clement's Inn, London, after the organisation commenced to grow, but the finances of the society being insufficient to keep such London offices going, the society's work for the last few years has been conducted from the offices of the secretary, at Worcester.

A Bill was prepared by the secretary and solicitor known as the "Trades Poisons and Poisonous Compounds Bill," and the provisions of this Bill were brought forcibly before the Board of Agriculture and the Lord President of the Privy Council, who, realising that some alteration in the law was required, appointed a Departmental Committee to consider the matter. The Traders' Society being the prime movers in the agitation, was asked to submit witnesses, which was done, with the result that in 1903 the Departmental Committee made their report, and recommended an alteration in the law on the lines of the Trades Poisons Bill.

Following this up, the society organised deputations to wait upon the President of the Board of Agriculture, and eventually the Government took the matter up and introduced the Poisons and Pharmacy Bill. Petitions were signed and presented to Parliament, and the agricultural and horticultural societies, and chambers of commerce were asked to co-operate in the effort which the Traders' Society was making to get the Pharmacy Act, 1868, amended; but it was only after much patient work and perseverance on the part of the Traders' Society that the Bill was successfully pioneered through Parliament, which was done last session, and has now become law.

G. H. RICHARDS.
234, Borough High Street, London, S.E.

FORTHCOMING ENGAGEMENTS.

MONDAY, January 11.—United Horticultural Benefit and Provident Society; committee meeting.

TUESDAY, January 12. — Royal Horticultural Society; committees meet at 12 o'clock; general meeting at 3 o'clock; Scientific Committee at 4 o'clock.

SATURDAY, January 23.—Annual dinner of the French Horticultural Society of London, at the Café Royal, at 6.30 p.m.; Sir Albert K. Rollit will preside.

The Selborne Society has revived the old title of its magazine, which will henceforth be called "The Selborne Magazine (and Nature Notes)," and will be published by Messrs. George Philip and Son, Lim., of 32, Fleet Street, E.C. All communications with regard to the society should be addressed to the Hon. General Secretary of the Selborne Society, 20, Hanover Square, London, as heretofore.

ECKFORD'S

When growing Sweet Peas, grow only the best. **The best that can be obtained are Eckford's 1909 NOVELTIES.**

Write for Catalogue giving full particulars of the special novelties for this season.

Special Novelty Offer.

One packet each of the 10 grand novelties, 9/- post free.

Villa (B) Collection.

CATALOGUES RECEIVED.

HENRY ECKFORD, WEM, SALOP.—Although this is a good catalogue of flower and vegetable seeds, it is especially notable as being the one to which we look first for sweet peas, as Wem is "the headquarters" for these flowers.

DICKSON AND ROBINSON, CATHEDRAL STREET, MANCHESTER.—A large, well-arranged, and freely illustrated catalogue of flower and vegetable seeds.

HORACE J. WRIGHT, DAULT ROAD, WANDSWORTH.—A handy vegetable and flower seed catalogue, prominence being given to sweet peas. It contains a coloured plate of Evelyn Hemus, Mrs. Henry Bell, and St. George.

PAUL AND SONS, CHESHUNT.—An excellent descriptive and illustrated rose catalogue for 1908-9. Many of the illustrations, representing the newer Cheshunt roses, have appeared in these pages.

DOBBIE AND CO., ROTHESAY.—The useful spring catalogue from this firm is well arranged, and full of interest. Seeds and plants are listed, and special features are made of sweet peas and dahlias.

C. W. BREADMORE, 120, HIGH STREET, WINCHESTER.—In this catalogue of vegetable and flower seeds sweet peas occupy by far the most prominent position, and this is what one would expect, remembering Mr. Breadmore's position as a grower and raiser of these flowers.

ALEX. DICKSON AND SONS, LIM., BELFAST AND DUBLIN.—An excellent and handy catalogue of flower and vegetable seeds, including several novelties in both departments.

NOW READY.

V1 FLUID
THE WINTER SPRAY FLUID.

THE PRIORY GARDENS, ROEHAMPTON, S.W. November 14th, 1908.

Sirs,—I purchased 2 gallons of V1 and sprayed about half the trees under my charge here, doing the other half with another preparation. I have much pleasure in saying that V1 has exceeded my expectations; the trees kept clean all the Summer, with the exception of a slight attack of Green Fly upon the young shoots of some plum trees, which was soon got rid of by an application of V2 Fluid. I have no hesitation in saying that if your two Fluids are as effectual in the future as they have been here this season, no one need have dirty trees or maggoty and misshapen fruits.

Yours respectfully, **D. CAMPBELL.**

V1 FLUID IS EASY TO MIX AND EASY TO APPLY.

1 Gallon of Fluid makes 100 Gallons of Spray Mixture.

Prices and Descriptive Booklet on application to:—

Wm. COOPER & NEPHEWS, Berkhamsted.

TO-DAY! AND FOR YEARS AND YEARS PAST the XL ALL Specialities are and have been the best on the market. Where is the Gardener who does not pin his faith to one or the other of these celebrated Insecticides or Fertilisers? XL ALL FERTILISER has pleased all who have used it this season. The Sales of XL ALL FUMIGATOR prove that it is more popular than ever. XL ALL LIQUID NICOTINE INSECTICIDE is always spoken of by gardeners and growers as the most deadly to Mealy Bug, Thrip, etc. XL ALL WINTER WASH for dormant Trees acts like magic, clearing the Trees and Bushes of all Insects' Eggs, Moss, and Fungoid Growths. XL ALL LAWN SAND, a weed eradicator and fertiliser for weedy and poor lawns. XL ALL WEED KILLER used once a year "No weeds can live." Please ask your Nurseryman, Seedsman, or Florist for a copy of my small pink list, giving particulars of these and many other XL ALL Preparations, which can be obtained from the Horticultural Trade throughout the World. G. H. RICHARDS, Manufacturer and Patentee, 234 Borough High Street, London, S.E.

FREEHOLD NURSERY FRUIT and POULTRY FARM to be SOLD, a bargain; brick-built residence standing in 2¼ acres; five greenhouses, orchard, 300 apple, plum, pear, and cherry trees, poultry houses, pond, paddock; main road; 20 miles London. Golf, hunting. Apply AMBROSE and SON, Loughton.

New Tomato "VICTOR."

This Tomato, the result of several years careful crossing and selecting, is, we have no hesitation in saying, the most prolific variety yet sent out. The fruit, which is of medium size, rich colour and splendid flavour, is borne in trusses of from 12 to 25 at every joint, and the plants are remarkably short-jointed. The flesh is wonderfully solid, and the seeds are few in number. Per packet, **1/-**

New Catalogue for 1909 Now Ready, Free on application.

DICKSON, BROWN & TAIT,
Corporation Street, MANCHESTER.

GIANT-FLOWERED SWEET PEAS.

Each Packet will contain 40 Seeds.

COLLECTION A, Price 1s., Post Free.—**Dorothy Eckford,** white; **Enchantress,** light pink waved; **Dora Breadmore,** buff; **Jessie Cuthbertson,** rose flake; **Coccinea,** cerise; **Black Michael,** maroon; **Hon. Mrs. Kenyon,** primrose; **Gladys Unwin,** pink waved; **Miss Willmott,** salmon pink; **King Edward VII.,** crimson; **Mrs. W. Wright,** mauve; **D. R. Williamson,** lavender-blue.

COLLECTION B, Price 2s., Post Free.—**Nora Unwin,** white waved; **Mrs. A. Watkins,** pale pink waved; **Henry Eckford,** salmon; **Queen Alexandra,** scarlet; **Helen Pierce,** veined blue; **Lady Grisel Hamilton,** lavender; **Mrs. Collier,** yellow; **Queen of Spain,** pearl pink; **Countess Spencer,** large, pink frilled; **Lord Nelson,** deep blue; **Horace Wright,** violet-blue; **Black Knight,** maroon.

NOTES OF THE WEEK.

◆

Periodic Growth.

One of the main peculiarities of most vital phenomena is their rhythmic or recurrent character. Like the tides of the ocean, they have their periods of ebbing and flowing, the pulse, as it were, of Nature; an alternation of activity and rest, instead of a constant even and uninterrupted progress. In the animal kingdom these periods may be of two kinds. Thus in man the alternation of day and night determines naturally periods of work and sleep, which in noctural animals may be reversed, while in hybernating animals the lack of food in the winter has determined a long period of dormancy during that season, independently of the shorter sleeping periods of the warmer seasons. The great underlying cause of this periodicity lies in the fact that the revolution of the earth on its axis, and its greater revolution round the sun, determine two different alternations, both determining in their turn a waxing and a waning in the vital stimulus of the solar rays of light and heat and electricity. Its diurnal revolution on its axis results in night and day, and its annual revolution round the sun, coupled with the fact that it spins aslant, and not perpendicularly, causes a sort of swing which, as we know, reduces the sunshine north and south of the tropics for six months in the year, and increases it in like ratio for the other six months, creating summers and winters of varying intensity as either pole is approached. In the great process of evolution of organic life, these oscillating phases have inevitably affected it accordingly. It is a first essential of continued existence that an organism should fit itself to its environment, and it is to the infinite variety of conditions brought about by, first, this cosmic variation of stimulus; second, the varied conditions of the terrestrial surface, and of the oceanic waters; and, thirdly, the inconceivably complex interrelations of organic life itself in the internecine struggle for existence, that we owe all the wonderful beauty of adaptation at which the student of Nature finds himself overwhelmed with admiration and awe. In the plant world the periodic growth is determined by two main factors, heat and cold, and humidity and drought. Warmth and humidity are first essentials to plant activity, the warmth as a stimulus, and humidity, or water, as a formative material. The seasons vary in character in different parts of the world. In tropical regions, for the reason already indicated, the amount of sunshine varies little from year's end to year's end, the sun rises and sets regularly at six o'clock a.m. and p.m. every day. Under such conditions plant periodicity is largely akin, as regards rest and activity, to that of animals, but, as a rule, owing to periodic winds, this uniformity is disturbed, and periods of drought and torrential rains occur which mean equal periods of rest and activity for the plant life of such regions. At high elevations, too, even in the tropics, as we ascend we find a gradual alteration in the climatal conditions as the temperature falls, but, of course, periodicity cannot be so well marked under these comparatively equable conditions as it is in temperate and arctic regions, where, at the poles, the extreme is six months day and six months night. In our own land it is easy to see how annual periodicity is practically enforced. The great bulk of our deciduous trees, did they refuse to shed their foliage, would be shattered by the first heavy fall of snow, from which even the evergreens often suffer greatly, although their glossy leaves or narrow needle-like ones, are designed to retain it as little as possible. Most of the herbaceous foliage is destroyed by frost, and it is, moreover, a well-recognised fact by all plant growers, that if continued growth be induced artificially, the vigour of the plant is as inevitably sapped and weakened as is the vigour of a human being persistently deprived of sleep. Nature, however, has no hard and fast rules, and thus in our early spring flowers, tulips, hyacinths, scillas, daffodils, crocuses, etc., we see exceptions to the rule of active growth in summer and rest in winter, since it is during the winter that their roots are active in preparing for the spring display of foliage and flower, while during the summer they have insisted upon resting, defying the blandishments of sun and shower, which have stimulated the great host of other plants to the utmost. Most of such exceptions are due, however, to the fact that the plants concerned are really the outcome of different environments in other countries, but manage to hold their own in this without sacrificing their native periodicity.

MR. A. D. WEBSTER,
Superintendent of Regent's Park, London.

Mr. A. D. Webster, whose portrait we have the pleasure of giving herewith, has for some years past occupied the position of superintendent of Regent's Park, and during the period in which he has been in charge of this magnificent open space he has given many proofs of his intimate acquaintance with trees and shrubs, and the conditions under which their charms are displayed to the best advantage. Mr. Webster has also worthily maintained the traditions of this fine park for the beauty of its floral displays, and annually visitors have had the opportunity of enjoying arrangements of both spring and flowering plants of the most charming description, and in the summer season horticulturists have had the opportunity of obtaining lessons of immense value in the association of plants remarkable for the beauty of their foliage with plants grown for their flowers. Some of the more noteworthy of the examples have been illustrated in these pages, and we have also given illustrations of the delightful effects produced by the culture of crocuses in the grass. Born at Balmoral, where his father was manager of woodlands to the late Prince Consort, Mr. Webster devoted quite early in life his attention to aboriculture, and achieved much success, as evidenced by his acting in the capacity of manager of woodlands to Lord Penrhyn, the Earl of Derby, and the Duke of Bedford, previous to his joining his Majesty's Office of Works twelve years ago. Mr. Webster is a Fellow of the Botanical Society, and Honorary Corresponding Member of the Royal Horticultural Society, and the author of several arboricultural, botanical, and horticultural works. These latter comprise, "Practical Forestry," "Foresters' Diary," "Hardy Ornamental Flowering Trees and Shrubs," "Hardy Coniferous Trees," "Flora of Kent," "Forest Flora of Carnarvonshire," "British Orchids," and "Greenwich Park and its Associations."

Berlin International Horticultural Exhibition.—The preparations that are being made for the international horticultural exhibition that will be held at Berlin from April 2 to 13 are being rapidly proceeded with. The exhibition will be held in the new halls of the Zoological Gardens, Berlin, which are described as being admirably adapted to a horticultural display on a large scale. The two halls forming the building will be converted into one. In the arrangement of the plants in these two halls an endeavour will be made to combine horticulture and art in such manner as will produce a harmonious effect. It is intended to reproduce the chateau and its gardens which the Emperor William has recently purchased in the island of Corfu. This chateau was built, and the gardens laid out, by Empress Eugenie of Austria, and it is proposed to transform the gallery and orchestra of one of the halls into the terrace of the chateau. The sum of about £700 is offered as prizes by the committee, and there are in addition numerous special prizes, among them being a prize of the value of £250, given by the City authorities.

Sicilian Fruits.—The complete destruction of Messina and the enormous amount of damage done to neighbouring towns has very naturally had the effect of turning the attention of the whole civilised world to the island of Sicily, which forms so important a part of the Italian kingdom. Notwithstanding its great natural attractions, this beautiful Mediterranean island has hitherto obtained but little attention from tourists, and is, in consequence, less known than many parts of Europe which are certainly not more interesting or attractive, or more accessible. Sicily has an area of 1,246 square miles, and is almost wholly devoted to agricultural pursuits. Large areas of land along the coasts are cultivated as vineyards, or devoted to lemon, orange, and olive groves, and by far the greater portion of the groves wherein lemons and oranges flourish are in the provinces of Messina and Palermo. The lemon and orange groves are chiefly on the slopes of mountains of moderate height, or on the lower slopes of those of considerable altitude, as it is found that the crops are heavier and the fruit of finer quality when produced by trees growing on high ground. Lemons are the most important of the Sicilian fruits exported in a fresh state, and it is a point of some interest that while oranges of equal and indeed superior quality are grown in other parts of the world, the lemons of Sicily are as yet unequalled in quality. Lemons that surpass them in appearance are grown in the district of which Naples is the centre, and at Murcia, so famous for its oranges, but in neither case are they equal to them in quality. In Sicily it has long been the practice to employ the bitter orange as a stock for lemons, it having been found that the trees when provided with foster roots are less liable to gum, and therefore retain their health and productiveness for a much longer period. According to the most recent available reports the gross annual return from the lemon groves ranges from £30 to £45, or about double that from vineyards. Almonds and hazel nuts are also largely grown for export.

Liverpool Horticultural Association. The annual chrysanthemum and fruit show of this association will be held on Wednesday and Thursday, November 3 and 4.

Food of British Birds.—Mr. Robert Newstead, M.Sc., A.L.S., has compiled a most interesting account of the food of British birds, and the records are based upon 871 post-mortem examinations of the stomach contents and the "pellets" or "castings" of 128 species of British birds. These are supplemented by field observations, making up a total of over 1,100 records. In the majority of cases the material was collected in the county of Chester, so the details concerning the dietary of the birds must be considered as more or less of a local character. A weak point is the great, or total, absence of spring and summer records, but Mr. Newstead has compiled these records as a suggestion for others to take up the work, rather than as a complete statement. However, taken in the aggregate, these records show clearly what an important part our British birds play in checking the increase and lessening the ravages of many of the pests of the garden and field. The records are issued as a supplement to the "Journal" of the Board of Agriculture for December, and as it can be obtained post free for 4d., we heartily commend it to all our readers who have any doubt as to the usefulness, or otherwise, of our native birds.

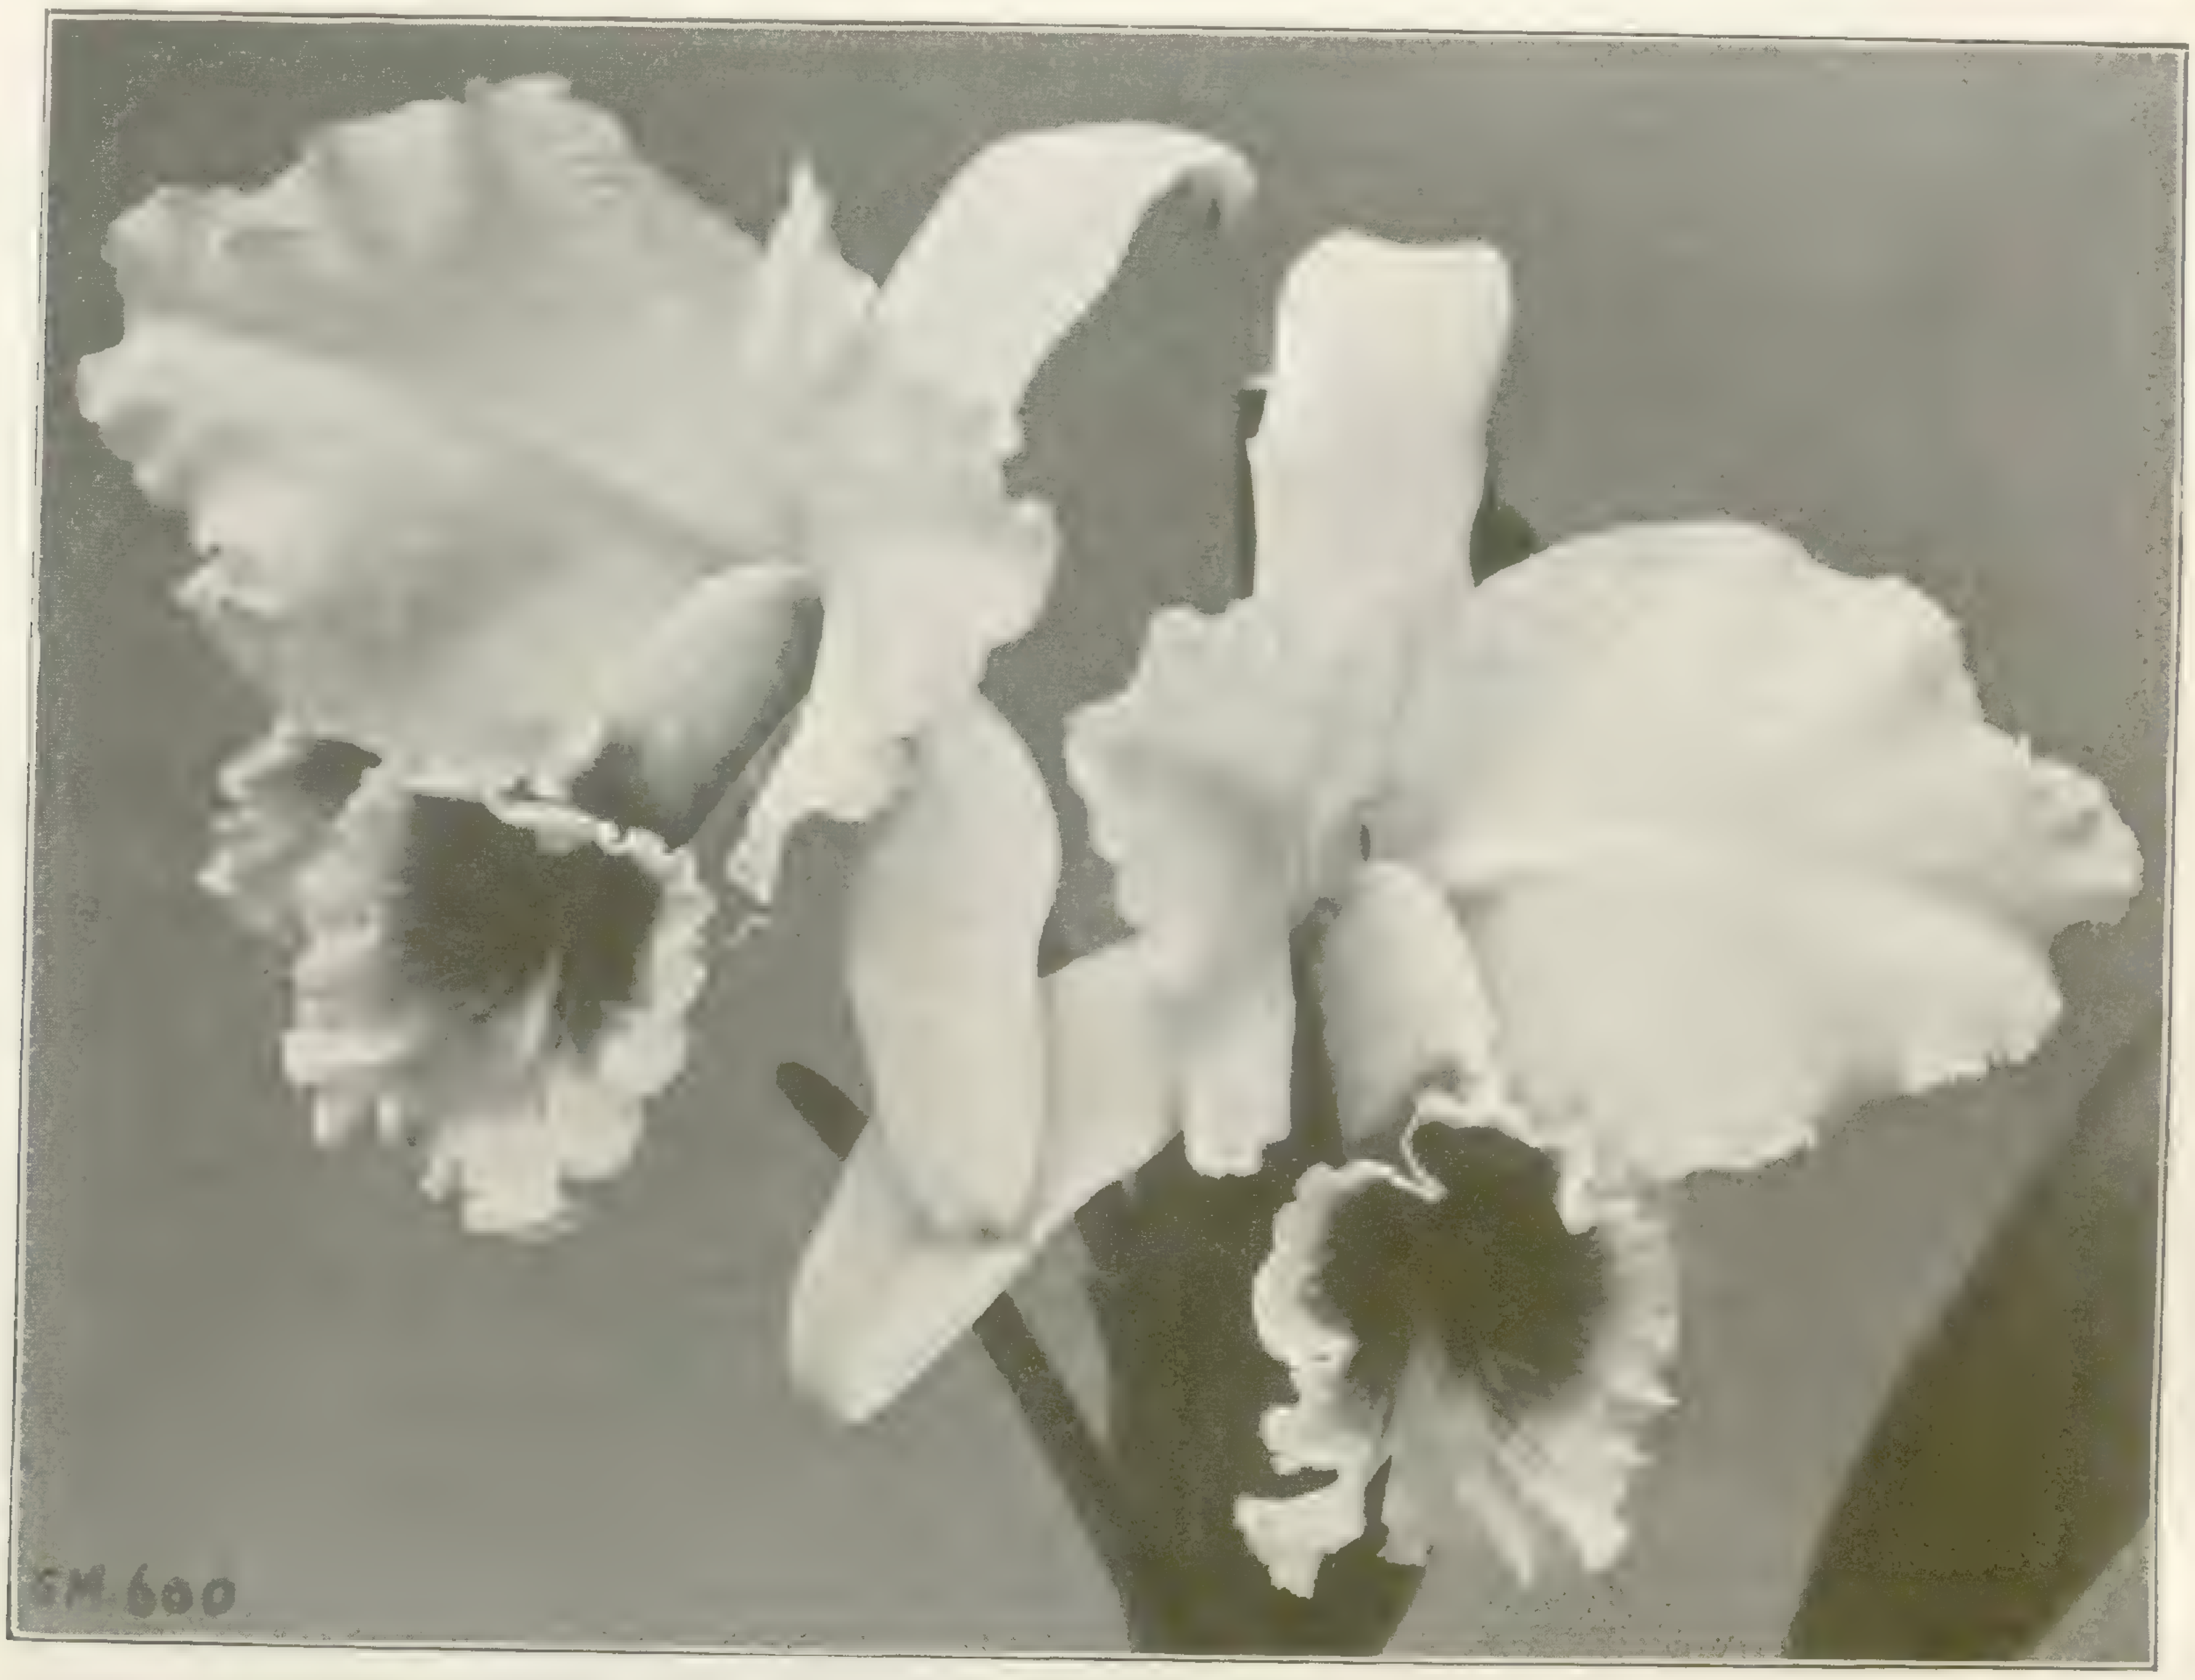
Fruit Imports, 1908.—The value of foreign fruits imported into the United Kingdom during the past year was considerably less than in 1907, and much of this shrinkage was due to the decrease in values in December last. The imports of apples during the twelve months ended with December last aggregated 3,376,579 cwt., of the value of £2,079,703, as compared with 3,526,232 cwt., of the value of £2,231,327 in the year previous. Of apricots and peaches the imports were 30,620 cwt., of the value of £60,141, or a decrease in quantity of about 8,000 cwt., and in value of about £18,000. Bananas were imported in larger numbers, but the values were lower, and the total was 6,385,449 bunches, of the value of £1,769,249. Cherry imports aggregated 160,479 cwt., of the value of £235,523, these figures representing a decrease of about 5,000 cwt. in quantity and an increase of about £36,000 in value. With regard to the imports of currants, the aggregate was 102,110 cwt., of the value of £121,852, these figures representing decreases, the drop in value being considerable. The imports of gooseberries were 44,518 cwt., of the value of £25,529, these figures representing a small decrease both in quantity and value. Grapes also show a decrease, the aggregate having been 673,673 cwt., of the value of £728,026. In the imports of pears there was an increase on the year, notwithstanding the big drop in December, the total being 523,029 cwt., of the value of £515,914. The imports of plums was also larger, the aggregate having been 402,881 cwt., of the value of £428,966. The imports of strawberries have for several years past decreased at the rate of about 10,000 cwt. annually, and the aggregate last year was 33,391 cwt., of the value of £45,791. The total value of the fruit and nuts imported in 1908 was £10,372,244, as compared with £10,722,239 in 1907.

Changes at the Kew Herbarium.—Consequent on his having reached the age limit Mr. W. Botting Hemsley, F.R.S., has retired from the position of keeper of the Herbarium, which he has occupied with singular success for some years past. Dr. Otto Stapf, F.R.S., principal assistant of phanerogams, has been appointed keeper of the Herbarium, and Mr. C. H. Wright, A.L.S., principal assistant of phanerogams.

"**My Garden Diary,**" published by Messrs. Sutton and Sons, is distinguished by its elegance and utility, and enjoys so high a degree of popularity that it invariably receives a warm welcome from both amateur and professional gardeners. The reminders bear the impress of being based on a thorough acquaintance with the garden and its work, and will be found of much service to all who are engaged in gardening. There are numerous selections of plants and blank spaces for memoranda. The cover is embellished with flowers of cinerarias printed in colours.

Gardeners' Royal Benevolent Institution.—The annual meeting of this institution will be held at "Simpson's," Strand, on Thursday next, the 21st inst., at 2.45 p.m. Mr. H. J. Veitch, V.M.H., treasurer and chairman of committee, will preside, and the business will include the election of eighteen annuitants and the consideration of the following notice of motion by Mr. W. A. Bilney, J.P., honorary solicitor: "That every person having attained the age of 70 years who is in receipt of an annuity from the institution, and is eligible for a Government old age pension of less than the maximum allowance of 5s. per week, or whose total income does not exceed £31 10s. per annum, may have such charitable annuity reduced as the committee may determine under Rule III. 6, so as to render him or her eligible to apply for a pension on the Government scale, provided always that such reduction does not involve the beneficiary in any pecuniary loss." In some quarters exception has been taken to this proposal, but it should be remembered that by effecting a reduction in the amount paid to annuitants over 70 years of age, the committee will be in a position to recommend a much larger number of candidates for election in future years than has hitherto been possible. This year there are 73 candidates, and as only 18 can be elected on Thursday, 55 will have to bear the bitter disappointment inseparable from a failure to obtain a position on the pension list. The annual friendly supper will be held after the annual meeting, also at Simpson's, at 6 p.m., when Mr. W. J. Jefferies, of Cirencester, will preside.

Vegetables of Foreign Growth were sent to the home markets in large quantities during the past year, although the supplies were less than in 1907, when the imports were exceptionally heavy. The potato imports amounted to 7,038,323 cwt., of the value of £1,970,216, as compared with 8,249,366 cwt., of the value of £2,371,545 in 1907. In the imports of onions there was a considerable decrease, the aggregate having been 7,896,108 bushels, of the value of £993,669, as compared with 8,645,048 bushels, of the value of £1,036,231, in the year previous. The imports of tomatoes were 1,168,283 cwt., of the value of £955,985, these figures representing an increase in quantity of about 25,000 cwt., and a decrease in value of £65,820.



CATTLEYA PERCIVALIANA CHARLESWORTH'S VARIETY.

A distinct and beautiful variety of this useful winter-flowering species, exhibited by Messrs. Charlesworth and Co., Hayward's Heath, at the R.H.S. Meeting on the 12th inst., when it received a first-class certificate. Sepal and petals white, and the labellum rich purple and orange.

Fighting the Coccus at Burnham Beeches.—It is not long since we drew attention to the enormous spread of the Beech Coccus on the fine trees at Burnham Beeches, and to the need of the adoption of strong measures for the eradication or reduction of this dreaded pest. We now learn that Mr. Duchesne, the superintendent, has taken advantage of the powers permitted him by the City of London's Corn, Coal, and Finance Committee, to follow up a regular system of spraying with a paraffin emulsion. Some good people who have no knowledge of the pest consider that now the trees have been sprayed there is an end to the infestation. We wish we could believe it. If the pest is to be kept under, then there must be no half-hearted attack, but rather a continuance of attacks by means of the most approved methods. The Beech Coccus is not a thing to play with.

Trials at Wisley in 1909-10.—Trials of the following fruits, flowers, and vegetables at the Royal Horticultural Society's Gardens at Wisley during 1909 have been arranged. Autumnal raspberries—15 canes of each variety to be sent at once. Tree carnations—four plants of each variety to be sent in February, two for out, two for indoors. Annuals—seeds to be sent in January. Garden dahlias, show, and cactus excluded—Two plants of each variety to be sent in April. Early-flowering outdoor chrysanthemums—two plants of each variety to be sent in April. Pentstemons—two plants of each variety to be sent in April or seed in January. Potatoes—each variety must be labelled as being "early," "mid-season," or "late"; 20 tubers of each to be sent by February. Also experiments with the same variety—viz., "The Factor" (20 tubers)—secured from as many varying sources as possible, under different soil and climatic conditions. Send particulars of soil and climate. Cauliflower—¼oz. of seed of each variety. Lettuce—¼oz. of each variety. Kidney beans—½ pint of each variety. All parcels should be addressed: if sent by post—The Superintendent, R.H.S. Gardens, Wisley, Ripley, Surrey. If by rail, to Horsley Station, L. and S.W.R., with advice by post to the superintendent.

Prizes for Botanical Investigations.—We learn from "Nature" that the French Academy of Sciences proposes to offer the following prizes for botanical study in 1909: The Desmazières (1,600 francs), for a memoir on cryptogams; the Montagne prize (1,500 francs), for work on the anatomy, physiology, development, or description of the lower cryptogams; the de Coincy prize (900 francs), for a work on phanerogams; the de la Fons-Melicocq prize (900 francs), for a work dealing with the botany of the North of France; the Bordin prize (3,000 francs), for a study of the origin, development, and disappearance of the transitory tissues which may enter at various periods into the structure of the vascular plant. To determine, in each particular case, the ephemeral role of the tissue considered.

Continental Gardens and Nurseries.—Mr. W. J. Bean, the assistant curator, Royal Gardens, Kew, spent twenty-four days on the Continent in June last, visiting famous continental gardens, parks, and nurseries, and in the recent issue of the Kew Bulletin he gives an account of his journey and a very interesting account it is. Among the chief places he visited were Brussels, Boskoop, Hessi's Nursery at Weenen, Herrenhausen Gardens, Berlin Botanic Gardens, M. Leon Spathe's Nursery, Sans Souci Gardens, Dresden Botanic Gardens, the Grosse Garden of Dresden, Dresden Botanic Gardens, Vienna Botanic Gardens, Schönbrunn, Ischl Forests, Munich, Lemoine's Nurseries at Nancy, Vilmorin's Nurseries at Verrieres—M. Buisson and M. Maurice de Vilmorin's Garden at Les Barres, with its rich collection of rare trees and shrubs. The account is well worth reading, as Mr. Bean accords praise or blame freely, and his criticisms are of special value.

BRACKEN AS LITTER.

The following important and interesting article, from the pen of Mr. Edward J. Russell, D.Sc. (Lond.), "Goldsmith" Chemist for Soil Investigation, Rothamsted Experimental Station, appeared in the "Journal" of the Board of Agriculture for October:

In many districts, especially where there are large stretches of sandy heaths, quantities of bracken are obtainable, and are in common use for litter. Its value for this purpose appears to be considerable, and farmers who use it speak well of it. A century ago Arthur Young praised it highly, advising farmers in September to "cut fern, called in some places brakes and brakens. This is most profitable work, and should never be neglected. Carry it into the farmyard, and build large stacks of it. . . You will be able to raise immense quantities of dung, and it is well known that no vegetable yields such a quantity of salts as fern, from which we are to conclude that it is well adapted to the making manure. The good farmer, in this work of bringing fern, should not confine himself to his own wastes, but purchase it of his neighbours." Whilst no careful comparison with straw seems to have been made, there is a fairly general opinion that bracken is nearly as useful as straw, so far as the animals are concerned, although a competent observer has noted that the animals' coats are not so good, indicating that they do not do quite so well on bracken as on straw. Litter, however, fulfils another important function besides ministering to the comfort of the animals; it has a great effect on the composition, and particularly on the value of the dung. This function only is dealt with in the present paper.

The simplest way of ascertaining the value of bracken as litter is to compare it with straw, which is by far the commonest of all littering materials, and would, as a matter of fact, be the alternative generally adopted on farms where bracken is used.

Litter contributes in at least three ways to the value of the manure. It absorbs and retains a number of valuable substances, including ammonia, that would otherwise escape as gas, and the easily soluble nitrogen compounds of the urine which might be lost either by washing out or by conversion into ammonia; the importance of this is evident when it is remembered that the nitrogen compounds most easily lost are those most "available" for the plant, and therefore of most value. It also absorbs potassium compounds which occur dissolved in the urine, and are liable to be lost in the drainage water. Secondly, when it decomposes it restores to the soil those food constituents which it had during its lifetime assimilated, and which obviously have been, and may again, become "available" as plant food. Thirdly, during the decomposition process the stems and leaves—the "long" materials in fact—are converted into black, sticky humus possessing properties of great value for improving the soil.

Bracken as an Absorbent.

All substances containing cellulose have the power of absorbing water, dissolved bodies, ammonia, etc., and consequently all dead plants, leaves, stems, sawdust, peat moss, and similar materials possess this property. They are not all equally good, however, and naturally those which can most readily take up and retain ammonia and soluble bodies are of most value as litter. Bracken, and especially the leafy part, is better than straw, while the hard stems have about the same value; both are, however, much below peat moss. Samples of straw and bracken were allowed to stand in contact with a weak solution of ammonia, and then left to dry for two days in the air. They all retained some ammonia at the end of this time, but not equal amounts, the relative figures being:

Bracken.			Straw.
Entire.	Leafy part.	Stems.	
70	100	33	30

It is evident that the superiority of the bracken is due to the leaves, which, being small, expose a large surface to the ammonia, and facilitate the process of absorption.

In another experiment bracken was tested against peat moss, and the relative quantities of ammonia absorbed from a weak solution were as follows:

Peat moss.		Bracken.
100	...	25

These figures, of course, cannot lay claim to any absolute value, since the relative proportion of leaf and stem in the bracken has so great an effect on its absorptive power; they show, however, that bracken is superior, weight for weight, to straw.

The power of retaining water and soluble substances varies in the same way; peat moss is best, bracken next, and straw third, and again bracken owes its power largely to its small leaves. These experiments were made with equal weights of material; if, however, an equal bulk be taken, bracken is inferior to straw as an absorbent because it is so much lighter.

The Composition of Bracken.

Although bracken has long been used in agricultural practice, very few analyses are recorded, and these show, as would be expected, a certain amount of variation because the composition of bracken depends to some extent on the soil on which it grows and also on the time of cutting. The young plant is richest in nitrogen and potash; before the leaf and stem die there is probably a transference of some of the food material to the root just as takes place in certain other plants, but a good deal is left behind, and the whole of this is secured if the bracken is cut in autumn, as usual, and kept sheltered from excessive rain. Of course, if it is left out during the winter, and not cut till after a great amount of washing has taken place a loss of substance is likely to result.

An important point about the composition of bracken is the large amount of nitrogen present; usually about 1.3 per cent. is found, and even higher figures are recorded. Straw, on the other hand, only contains about one-third of this, viz., .5 per cent. The amount of potash shows considerable variation, doubtless following the rather large variations in the small amounts present in the light gravelly or sandy soils where bracken commonly grows. English samples usually show about .1 per cent.; foreign samples are considerably higher. The potash content of straw is also liable to variation, but the average is probably somewhere between .6 and 1 per cent., so that straw is much richer than bracken in this constituent. The phosphoric acid in bracken is about .2 per cent.; straw contains about the same. In the following table are given (1) analyses made by the writer of samples from Haslemere and Harpenden respectively; (2) the average composition calculated from all the analyses the writer has been able to find; (3) the average composition of English samples. For purposes of comparison the average composition of wheat straw is also included:

—	Dry Matter.	Total Mineral Matter.	Nitrogen.	Phosphoric Acid.	Potash.
Bracken from Haslemere (Sept.)	84·36	5·87	1·30	0·19	0·16
Bracken from Harpenden (April)	83·19	3·61	1·00	0·11	0·06
Average of all analyses, English and foreign ...	...	5·12	1·33	0·26	0·50
Average of English analyses only*	86·37	4·70	1·44	0·20	0·11
Wheat straw	86·4	5·3	0·48	0·22	0·63

* Includes analyses kindly supplied to me by Dr. J. A. Voelcker and Mr. John Hughes.

The low value for the Harpenden sample, collected in April, after it had been lying on the common exposed to the bleaching action of the winter rain, is interesting.

It is evident that bracken is richer than straw, and the difference in value comes out still more clearly if we work out the manurial value on the unit system. There is some difficulty in fixing values in the case of bracken and straw, but on a moderate estimate, taking the value of nitrogen as 5s. per unit, of phosphoric acid as 3s., and of potash as 4s., the value as manure of English bracken in the above table is 8s. 6d. per ton, and of wheat straw 5s. 6d. per ton. Bracken is, therefore, 50 per cent. more valuable than straw, so far as its content of fertilising materials is concerned.

(To be continued.)

OPPORTUNISM.

"There is a tide in the affairs of men,
Which, taken at the flood, leads on to fortune;

Omitted, all the voyage of their life
Is bound in shallows and in miseries.
On such a full sea are we now afloat;
And we must take the current as it serves,
Or lose our ventures."

—Julius Cæsar, Act IV., Sc. 3.

A really successful gardener must be many things, but one thing especially he must be in this uncertain climate of ours, and that is an opportunist, which, for the benefit of young readers, I may define as a man who takes advantage of opportunities, and when his circumstances will not adapt themselves to him adapts himself to his circumstances. We all know him in the farming profession, the man to whom we always look to be the first to finish sowing in the spring as he is the first to finish haying and harvest, while his neighbour, the afternoon farmer, having only three or four more days' work to do when the weather breaks up, is another month before he can finish. The opportunist, either in farming or gardening, divides work into two main classes—that which can be done at any time within certain limits, and that which can only be done under certain favourable conditions, and he never spends a minute upon work of the first class when it is possible to do work of the second.

If we apply this maxim to gardening practice we shall employ, say, a dry spell in November in doing work which can only be done at that season and under the prevailing conditions, such as any bulb planting, the transferring of plants from the nursery beds to their permanent positions, the planting or removing of fruit trees, and the numerous other jobs which make a nice November such a busy and enjoyable time for the gardener who looks ahead. Such a one will not waste time at such a valuable season, which may end any day, in pruning trees, cutting down herbaceous perennials, clearing up leaves (more than is absolutely necessary), and other work which can be done as well in damp weather as in dry.

Similarly, on a dry day in March, when the soil is like an ash heap after the recent frost, which went away without rain, such a one will not waste a minute more than is necessary doing work in the houses or the potting shed, when he may get in his early potatoes, carrots, and peas, under such perfect conditions.

The carrying out of this principle every day all through the year in arranging the routine work of the garden, will mean that, like the farmer who always finishes sowing or harvest first in his district, the gardener will generally be ahead of his neighbours in point of time, and generally, as a consequence, in results, too. It is only carrying out the principle of the homely saying that "the early bird catches the worm," the said early bird knowing perfectly well that he can sit on the tree and sing for hours after the drying wind and men have driven the worms far into their burrows.

ALGAR PETTS.

ARENARIAS OR SANDWORTS

There are among the arenarias or sandworts many weeds, but there are also many choice garden flowers, and these are, as a rule, eminently suited for the rock garden. They seldom present many difficulties in the way of cultivation, and, if given reasonable conditions at first, require little attention for years at a time. This cannot be said of many alpine flowers, and it is no slight merit for such useful plants to possess. They are generally pleasing alike in foliage and in flower, and several are of surpassing beauty, giving us sheets of snowy-white flowers or an abundance of lovely starry blossoms of the greatest beauty.

Generally speaking, their true places are the rock garden and the wall garden, but some may be employed as carpeters for taller plants and others may be utilised, when supported by stones, for edging the herbaceous border. The rock garden is, however, the true home for the arenarias, where they can spread into little carpets of green, covered in their season with snowy, creamy, or pinkish flowers. Their cultivation presents, as a whole, little difficulty, and in discussing the genus as a whole in detail, it will suffice to say that the plants in general like a sandy soil, plenty of stones, and a fair amount of sun, except where mentioned in the following notes, from which I have excluded the sandworts that are practically of no garden value.

ARENARIA MONTANA IN THE ROCK GARDEN AT MULLABODEN.

Arenaria balearica.

Were one limited to, say, two species or arenarias this would almost undoubtedly be one of the two. No flower of its size presents so attractive an aspect to the lover of alpine flowers as this, and when seen in its fullest beauty in May and June, although it lasts longer in some seasons and places, it is one of the most exquisite of alpines, with its tiny foliage clinging close to the stones and profusely spangled with tiny white flowers, of starry shape, and on short wiry stalks, just above the carpet of greenery. We have nothing like it in the range of alpines. It is of easy culture, but dislikes to be fully exposed to a hot sun. Shade, and a red sandstone over which to cling are its great luxuries. Any porous stone will do, and it will even live on dry soil without stone if the district is not too wet, but the old red sandstone seems to suit it particularly well. Shade it must have to some degree, and an experimental planting I made a year ago on two sides of a path emphasised my former experience in this way. I have used it as a carpeter, but it is most at home creeping up a stone. It is increased by division and by means of seeds.

Arenaria ciliata.

But little taller than A. balearica is the ciliate sandwort, A. ciliata, growing about three inches high, but erect in habit. It is inferior to several others, and may well be omitted where these are grown. It also has white flowers of considerable purity. It is suited to the rock garden on the level or a slope of small gradient.

Arenaria gothica.

This beautiful little sandwort is now achieving the favour it deserves, especially when it is grown under dry conditions among limestone, which it appears to prefer. It should only reach a height of some three inches, but under cultivation it has a tendency to become a little taller. It makes little dark green ovate leaves on stems which bear wonderfully pretty shining white flowers, large for the plant and of almost dazzling whiteness. Kept in the poorest soil, among stones, A. gothica will retain its alpine character better than in rich soil, and keep its rather trailing habit and the purity of its blossoms.

Arenaria grandiflora.

Partaking much of the character of A. montana, this is, under some conditions, hardly distinguishable from it, especially if the latter is well grown. It has, however, fewer but larger flowers, and on the rockery, trailing over stones and covering a large space with its dark green leaves and shining white flowers, it is of splendid effect. It has a tendency to run at the roots, but, although a good grower when established, young plants are difficult to make at home. It seems to like a fairly moist; but well-drained soil, well up on the rockwork. It is increased by division.

Arenaria graminifolia.

I have now known this plant for many years, but it is not one which I care about. It has long, rather grassy leaves, is of trailing habit, and gives a number of very small dull white flowers. It is pretty widely cultivated in nurseries, but does not deserve the prominent position sometimes given to it.

Arenaria Huteri.

Huter's sandwort is not yet in general cultivation, but it is one of real worth, and in a few years is likely to be more generally introduced into gardens. It is only an inch or two high, and has wiry little stems and flowers which are large for the size of the plant they adorn. These blooms are pure white. This sandwort revels in stones, but must not be too dry at the roots, although in a thoroughly well-drained position.

Arenaria Ledebouriana.

Although the flowers are small, and not so white as those of many of the other arenarias, I like Ledebour's sandwort, which has fine, grassy leaves, and many little flowers on wiry stalks. They are not so thickly set on the plant as are those of some, but they always seem to me to give a pretty lacelike aspect to the tuft which appeals to me. In poor sandy soil, with freestone chippings it is doing well with me.

Arenaria montana.

The accompanying illustration, which shows a plant in the rock garden at Mullaboden, is full justification for saying that this, with A. balearica, would be chosen by the present writer were he limited to two sandworts. It is "a joy for ever" with its masses of dark green leaves trailing over the stones, and covered with many large pure white blooms of much beauty. Its flowering is so dense that at times hardly a leaf is seen. The mountain sandwort will thrive well up on the rockery as well as near its base, and its only fault is that it is inclined to run a good deal at the roots —a tendency which must be guarded against as other plants will thus be imperilled. A gem of the first water, however, A. montana is an indispensable thing.

Arenaria purpurascens.

The purplish sandwort is a valuable plant when it can be obtained true. It gives us a mass of trailing glossy leaves, all starred over with pretty pale lilac blossoms. It is very distinct from the others in its colouring, and deserves a good place in a sunny situation among loam, sand, and grit. Over a stone it is a really pretty sandwort.

Other Species.

Among the other desirable sandworts are Arenarias laricifolia, pinifolia, and Rosani, all of which have biggish white flowers on slender stems, and make good carpets of pretty green foliage. They resemble each other considerably. Norvegica, again, is allied to gothica, but less desirable. Verna, however, deserves a note to itself, because of its value as a carpeter. It is ofttimes called cæspitosa, and is well known under that name. It makes moss-like carpets covered with starry white flowers. The golden-leaved variety aurea, is more used for carpeting and flowers less freely. There is also a charming variety of A. verna with dainty little double white flowers, but it appears to be of a delicate constitution, and unfit to bear the vicissitudes of alpine flowers grown in the open. Where it will thrive, however, it is a fascinating little thing indeed.

These little sandworts are among the most charming of our alpine flowers, and will continue to increase in favour, so beautiful are they at all seasons as a rule.

S. Arnott.

Wyken Pippin Apple.—This apple is grown by myself, but I see no value in it at all. With me it does not crop freely, and the fruit is much too small to be useful. My trees are grafted on Ecklinville, which makes a good stock for most varieties. Although this apple may have a certain amount of flavour, it is distinctly "dry," too much so to be pleasant, and to justify my opinion that it is an apple not required, although some persons seem to have a weakness for it. —S.

Rainfall at Leonardslee, 1908. —It may appear strange, but most of the rain fell at night time. Rainfall in 1907 was 25.94in. :—

W. A. Cook.

BEGONIA IMPROVEMENTS.

It must be fully apparent to even the most casual observer that one of the most striking phases of present-day floriculture is the continued improvement among begonias. The extreme variability of begonias and the way in which they have lent themselves to the skill of the hybridist has resulted in the origination of a wonderful diversity of form, colour, etc., and also of entirely new types.

With reference to winter-flowering begonias, it is pleasing to note the influence of B. socotrana in the favourites of to-day. Since its discovery in 1880, it has been so successfully utilised that the majority of the best winter-flowering varieties owe much to it. Such widely divergent types as Gloire de Lorraine, and the semi-tuberous sections, gain much from its influence.

Gloire de Lorraine and its varieties are wonderfully popular, and the wealth of colour which they give in the conservatories during the dull months is very great. Even in trade circles this type of begonia is very largely grown. The sports which have been obtained from the type have given additional interest and beauty, and the manner in which the Lorraines are spoken of is but a surety of their popularity. Such varieties as Caledonia, Turnford Hall, Mrs. L. de Rothschild, The King, and others are evidence of its sportive character, and show that improvements can be obtained by taking advantage of this characteristic.

Another notable advance is among the hybrid forms, obtained by crossing socotrana with tuberous-rooted varieties. These, which include such well-known forms as Ensign, Winter Cheer, John Heal, Mrs. Heal, Winter Perfection, are enriched by the more recent novelties, such as Bowdon Beauty, double rosy-pink; Elatior, double carmine, bright and free; Winter Glow, double fiery red; and the pretty double pink Julius. The glorious novelty Patrie, is most free in blooming, and is somewhat like the Lorraines in flower and foliage, but slightly larger. Its parentage is B. socotrana crossed with a deep yellow variety of B. Pearcei, and this has given to Patrie a glowing salmon colouring, shading nearly to gold. It is remarkable for its beauty and freedom, and for its long duration, which is from November until April. That this variety will prove a welcome addition one does not doubt in the least, especially as it responds to good treatment as readily as the Lorraines.

A blending of the qualities of B. socotrana with B. semperflorens, or B. Dregei should result in some pleasing, easily-grown varieties, and really one cannot have too many good begonias for winter flowering. "After winter, the spring," and while the winter begonias are still in our midst, we are thinking of those which are to display their beauty abroad during the summer months.

Improvements are especially noticeable among the bedding begonias. We now have such sterling bedding doubles as Argus, a floriferous bright scarlet; Colonel Laussedat, a charming yellow, very dwarf and free; Gambetta, a glorious glowing orange, strong and vigorous in growth and blossom; Lafayette, a rich crimson, of good habit; Washington, a well-known gem; and the new Rouget de l'Isle, a magnificent double scarlet of remarkable beauty, superior to Lafayette in all points.

The variations which occur in the tuberous begonias are already well known, and such selected strains as Crispa, with its lovely forms and colourings; Cristata, with its quaint crested blossoms; and the curiously spotted Marmorata, with its scarlet and crimson flowers, heavily marked with white, will readily occur to the mind of the reader, as representing the strides which have been made in this direction. In addition, we have now from different sources some fine double strains, both of Cristata and Marmorata, both of which are pleasing in the double form.

Scented begonias are also receiving much attention from Continental raisers, and a group of hybrids raised by crossing selected forms of B. Pearcei with B. Baumanni, combine, with rosy-salmon colouring, a pleasing fragrance. Extremely notable in this direction are the improved double forms of B. odoratissima, and anyone making a selection of begonias for indoor decoration during the coming season should endeavour to secure a few of these forms. With good sized, erect blossoms, rounded leaves, and a charming tea-rose scent, these double begonias are certainly notable acquisitions; Alba plena, double white; Rosea plena, double pink; and Rubra plena, double crimson, are very pronounced varieties. The crossing of B. Baumanni, with selected single begonias and steady re-selection of the seedlings, has resulted in a good strain of singles, with a noticeable fragrance.

Attention is also being paid to the daintier types of bedding begonias, of which B. Boliviensis and B. Worthiana are pleasing examples. The extreme value of this class has led to a widespread adoption of them for bedding and for other decorative purposes. One of the best novelties of late years was Bertini, a popular rich red, of good habit. This is now followed by Bertini nana, a very dwarf, compact edition of the well-known form, which should be very serviceable for small beds or for edging.

P. S. Hayward.

RAMBLING ROSES IN POTS.

During the last few years a remarkable change has been brought about in the material for conservatory decoration through the spring months. Leaving entirely out of the question all retarded subjects and forced bulbous plants, we have now a vast number of beautiful flowering trees and shrubs that lend themselves to forcing, and which provide wonderful displays of bloom at a quite low cost. Roses have ever been favourites, and much time, skill, and money have been expended on producing early blooms for the conservatory or the home. Not seldom, when H.P. varieties alone have been used, the results have not been commensurate with the cost of production, but now that we have so many free-flowering H.T. varieties that do well and are fine for cutting, better results follow. For conservatory decoration, however, nothing can exceed in beauty or usefulness many of the exquisite rambling roses, notably those descended from Rosa Wichuraiana. So popular have these become that there is not the slightest difficulty in obtaining strong, well-established young plants in pots suitable for gentle forcing. The canes may be long, but if a short time before they come into flower these are bent to form a fan-shaped or other design, a wealth of flowers is presently produced and set out in a most attractive manner.

Strong, established plants, attention to cleanliness, very little heat to begin with, ventilation as growth proceeds, and good feeding with liquid manure, are the chief points to remember in the production of fine decorative plants. Dorothy Perkins, Lady Gay, Hiawatha, Tausendschon, Crimson Rambler, and Blush Rambler are all good for the purpose.

CANARY GUANO,

"The Best in the World"

For GARDEN and GREENHOUSE.

Canary Guano ensures perfection in Flower, Fruit, and Foliage; there is nothing like it for producing luxuriant growth.

Thousands of Prizes are obtained by its use every year.

It is used in the Royal Gardens and by leading professional gardeners and principal trade growers throughout the kingdom.

Sold in Tins, **6d.**, **1/**, and **2/6** each.

Bags: 14 lb., **3/6**; 28 lb., **6/-**; 56 lb., **11/-**; 1 cwt., **20/-** each.

Canary Guano may be obtained through any Seedsmen, or direct from the manufacturers –

SPECIAL NOTICE **SWEET PEAS** FOR 1909.

IF YOU WANT

REALLY GOOD SWEET PEAS

AT MODERATE PRICES, send to

ROBERT SYDENHAM, LIMITED, 33, Tenby St., Birmingham.

No Flowers give so much cut bloom at so little cost and trouble as Sweet Peas.

SPECIAL COLLECTIONS FOR 1909.

For fuller descriptions of the varieties mentioned in this list, and all other known varieties, we refer our friends to the little book, **"ALL ABOUT SWEET PEAS,"** revised and corrected to end of 1908. **Price 6d.**

The seeds in these Collections are all carefully hand picked; only plump, round seeds sent; all small, poor, or doubtful ones are taken out, which we do not think is done by anyone else in the trade; eighty to ninety per cent. guaranteed to germinate if treated as instructions sent with each collection.

EACH PACKET in Nos. 1, 2, and 3, CONTAINS 50 PLUMP, ROUND, SELECTED SEEDS.

Buyers not wanting any collection complete, may select their own varieties from EITHER COLLECTION, where priced at prices mentioned, and have 2s. 6d. worth for each 2s., or five packets of any one variety at price of four.

COLLECTION No. 1.—Twelve Useful Varieties, 1/3.

Coccinea, dark carmine scarlet; **Dainty,** white, with slight pink edge; **Dorothy Eckford,** white; **Evelyn Byatt,** orange and crimson bicolor; **Henry Eckford,** orange scarlet; **Hon. Mrs. Kenyon,** pale primrose; **Miss Willmott,** salmon-red; **Mrs. A. Watkins** or **Gladys Unwin,** waved pink; **Navy Blue,** deep violet blue; **Prince of Wales,** rich rosy crimson; **Romolo Piazzani,** rich blue; **Salopian,** deep mulberry red.

COLLECTION No. 2.—Twelve Good Varieties, 1/9.

A. J. Cook pale lavender purple; **Black Knight,** bronzy chocolate; **Countess Spencer,** large wavy pink; **Duke of Westminster,** rosy violet; **Herbert Smith,** orange and crimson bicolor; **King Edward VII.,** rich crimson; **Lady Grisel Hamilton,** pale lavender; **Mrs. Collier,** pale primrose; **Nora Unwin,** waved white; **Queen of Spain,** salmon-pink; **Sybil Eckford,** creamy buff, flushed pale pink; **Triumph,** rosy salmon and blush.

SINGLE PACKETS OF ANY VARIETY IN COLLECTIONS Nos. 1 and 2, 2d. each.

COLLECTIONS Nos. 1 and 2, when bought together, will be 2 6,
and a packet of "Millie Maslin" and "John Ingman Seedlings" will be added free of charge.

COLLECTION No. 3.—The Twelve Best Varieties, 2/-.

Clara Curtis, syn. **Primrose Spencer,** waved primrose; **Etta Dyke,** syn. **White Spencer,** waved white; **Frank Dolby,** waved lavender; **George Herbert,** waved carmine and rose; **Helen Lewis,** waved orange and rose; **Helen Pierce,** marbled blue; **Jeannie Gordon,** carmine and buff; **Lord Nelson,** dark blue; **Mrs. Hardcastle Sykes,** waved blush pink; **Mrs. Walter Wright,** rich rosy mauve; **Paradise,** rich pink, the best of the **Countess Spencer** type; **Queen Alexandra,** the best crimson scarlet.

SINGLE PACKETS OF ANY VARIETY IN COLLECTION No. 3, 3d. each.

COLLECTIONS Nos. 2 and 3 may be had together for 3/-,
and a Packet of "Phenomenal" and "Agnes Eckford" will be added free of charge.

SPECIAL PRICE FOR THE THREE COLLECTIONS, 4/-

and when bought together, the four added packets, and a packet each of the four best striped varieties, **Jessie Cuthbertson, Mrs. J. Chamberlain, Marbled Blue,** or **Hester** and **Unique,** will be added free of charge, making 44 of the very best varieties in cultivation, at an average cost of about one penny a packet.

PRICE OF EITHER OF THE EIGHT ADDED VARIETIES, IF WANTED ALONE, 2d. EACH.

COLLECTION No. 4.—The Twelve Newest Varieties, 4/-,

or what we consider the best of the Newest.

SPECIAL NOTICE.—The number of seeds in each packet in Collection No. 4 varies. The number is stated in black figures after each name, and where the packets can be sold separately the price is stated as well. There are about two thousand packets of these priced varieties, apart from what is anticipated will be sold in the collections. When these are sold orders can only be taken for the full collection, which is put at a specially low figure. Any variety not priced cannot be sold apart from the collection.

Apple Blossom Spencer (20), rosy pink and blush, waved, **6d.**; **Audrey Crier, (10),** bright rosy pink, waved; **Evelyn Hemus (15),** waved primrose, with picotee edge of pink, **6d.**; **Jet (50),** the darkest of all Sweet Peas, **3d.**; **Mother o' Pearl (Aldersey) (25),** a beautiful silvery lavender, slightly hooded and sweetly scented, **4d.**; **Mrs. Routzahn Spencer (10), the gem for 1909,** a buff or pale primrose ground shaded with salmon pink, a much improved **Mrs. Henry Bell, 6d.**; **Paradise Carmine (15),** a large waved, carmine and rose; **Queen Victoria Spencer (10),** a waved deep primrose, slightly shaded pale rose; **Saint George (15),** a grand orange scarlet, **1s.**; **Sutton's Queen (25),** a buff ground **Countess Spencer, 4d.**; **The King (12),** a fine waved form of **King Edward VII.**; **The Marquis (12),** large waved rosy mauve.

COLLECTIONS Nos. 3 and 4 may be had together for 5/-,
and a packet of the New White Everlasting Pea, WHITE PEARL, 25 seeds, added free of charge.

SPECIAL PRICE FOR THE FOUR COLLECTIONS, 7/-

which, with the nine added varieties, will be 57 in all, and making it the best collection, considering the varieties, ever offered for the money.

A few packets of Mr. Hugh Aldersey's celebrated SYEIRA LEE (20 Seeds), 1s.; sold as not quite fixed. Mr. Malcolm's MRS. A. MALCOLM (25 Seeds), 1s.; (10 Seeds), 6d.; CHRISSIE UNWIN (20 Seeds), 6d.; JOHN INGMAN (50 Seeds), 3d.; re-selected, but not guaranteed as quite fixed. ROSIE SYDENHAM (20 Seeds), 4d.; not quite fixed; also ROMANI RAUNI (Aldersey) (20 seeds), 1s., sold as not quite fixed.

THE GEM for 1909 is MRS. ROUTZAHN SPENCER,
this should be ordered at once. 6d. a packet of 10 Seeds, or 5 packets, 2s.

CHOICE MIXED SEEDS of most of the above, and other varieties, 2d. per packet of about 100 seeds; 6d. per ounce of about 350 to 400 seeds; 1s. 6d. per ½ lb., or 5s. per lb. of about 5,000 to 5,500 seeds.

ALL OTHER SEEDS EQUALLY CHEAP AND GOOD.

FULL LIST POST FREE ON APPLICATION.

(Half natural size.)

NEW COOKING APPLE, REV. W. WILKS.

(Peasgood's Nonsuch x Ribston Pippin).

A Strong Grower and Free Bearer.

Award of Merit (unanimous) from the Royal Horticultural Society.

On **DECEMBER 22nd, 1908,** Messrs. **VEITCH'S APPLES and PEARS** once more gained the Royal Horticultural Society's

GOLD MEDAL.

(See Illustration on page 51 of this paper.)

Inspection of the FRUIT TREES, GRAPE VINES, etc., growing at Langley and Feltham is most cordially invited.

NATURALLY-GROWN LAURELS.

Of late years a great deal of abuse has been heaped on the common laurel, and efforts have been made to oust it from the garden, which, in some instances, have been attended with a considerable amount of success. This is rather a pity, as when naturally grown and fully developed, the laurel is a very ornamental and useful evergreen, which thrives in a variety of positions, and has the advantage of flowering freely. Undoubtedly, a few years ago laurels were greatly overdone in gardens, and because of their cheapness they were planted here, there, and everywhere, without any thought as to their appropriateness or otherwise for the various situations. Then, instead of allowing the plants to develop into fine specimens, they were regularly clipped hard back each year, usually in the form of sloping banks. This occurred in almost every garden one entered, and naturally-grown bushes were the exception.

These banks of laurel in every conceivable position were very monotonous, and by their repeated occurrence gardens were frequently void of interest so far as shrubberies were concerned. This was not, however, the fault of the plant, but the manner in which it was abused, and a finely developed laurel is a very stately and handsome shrub. A fully-grown specimen may be anything from 12 to 18ft. in height and more than that in diameter, with a free branch arrangement and dense leafage, the leaves being large, glossy, and of a rich shade of green. To be seen at their best laurels should be planted to form isolated specimens or be placed singly in shrubberies, where they can develop freely. They are not fastidious regarding soil, as they thrive in that of a sandy character and also in loam of considerable density. They may also be planted in full sun or in partial shade.

When selecting plants to form specimens preference should be given to those which show a free habit of branching and bear large leaves. Forms are in commerce which possess a very dense habit, but these do not form such handsome specimens as the others, whilst those with small or thin leaves are less satisfactory than those which bear large foliage. Of the numerous varieties good ones are camelliæfolia, colchica, latifolia, and Otini. The latter is very distinct by reason of its large oval leaves, which are of a very dark hue. The variety camelliæfolia is a very strong grower, and is sometimes trained to form a standard, the trunk attaining a considerable size. It is also known as magnoliæfolia. Mature plants usually bloom each spring, every branch being laden with racemes of white or creamish coloured flowers, which are borne from the leaf axils. Should a large example show signs of becoming ragged, the shortening of a long shoot here and there is usually sufficient to coax it back into shape.

D.

ASPERULA ORIENTALIS; A USEFUL BLUE-FLOWERED ANNUAL.

ASPERULA ORIENTALIS.

When selecting hardy annuals for the border this charming free-flowering species should not be overlooked. It grows about a foot high, and produces an abundance of its terminal heads of sky blue sweetly scented flowers from July till October. It is admirably adapted for bouquet making, lasting well when cut. It rejoices in an open, sunny position, and keeps quite fresh where many annuals become dried up on our light, dry soil. It is native of the Caucasus, and is also known under the names of A. azurea and A. azurea-setosa.

E. J. Allard.

Cambridge Botanic Gardens.

ESPALIER FRUIT TREES.

Young apple and pear trees which have not reached their proper height should have their main upright growth cut back to a bud immediately above two others which are well situated for producing the next tier of branches. Shorten the leaders on the horizontal growths back sufficiently to ensure the development of the dormant buds. Keep the laterals well spurred in by pruning them back to within an inch and a-half of their base. Older trees, which have filled their allotted space, should have their leaders treated as laterals, and be pruned as already advised. Old trees are frequently found to have a superfluity of fruiting spurs, many of them projecting somewhat farther from the branches than is required, and these, at the same time, are not conducive to the health of the buds which are growing near their base by excluding from them both light and air. These long and often useless spurs should be shortened back to within an inch from the main branch, from whence, if the tree is in a healthy condition, young growth will push forth. Remove every old tie each season to prevent possible loss of some of the branches later on. A good opportunity is offered, when the trees are released from their supports to clear the branches from such pests as woolly aphis and the mussel scale, which are often found on the underside of the branches, and also on that part of the branch which is in contact with its iron or wood supports. Such positions are generally difficult to reach with the sprayer. Scrub the branches well with some soapy water, using a stiff scrubbing brush, and working the point of the brush well into the crevices to dislodge the aphis, and well around the base of the buds, and the whole of the main stem and branches, to remove the scale. Make the trees secure by refastening them in their proper positions to the supports, always allowing plenty of space for the future swelling of the branches, more especially on young trees.

George Woodgate.

ROSE HEDGES.

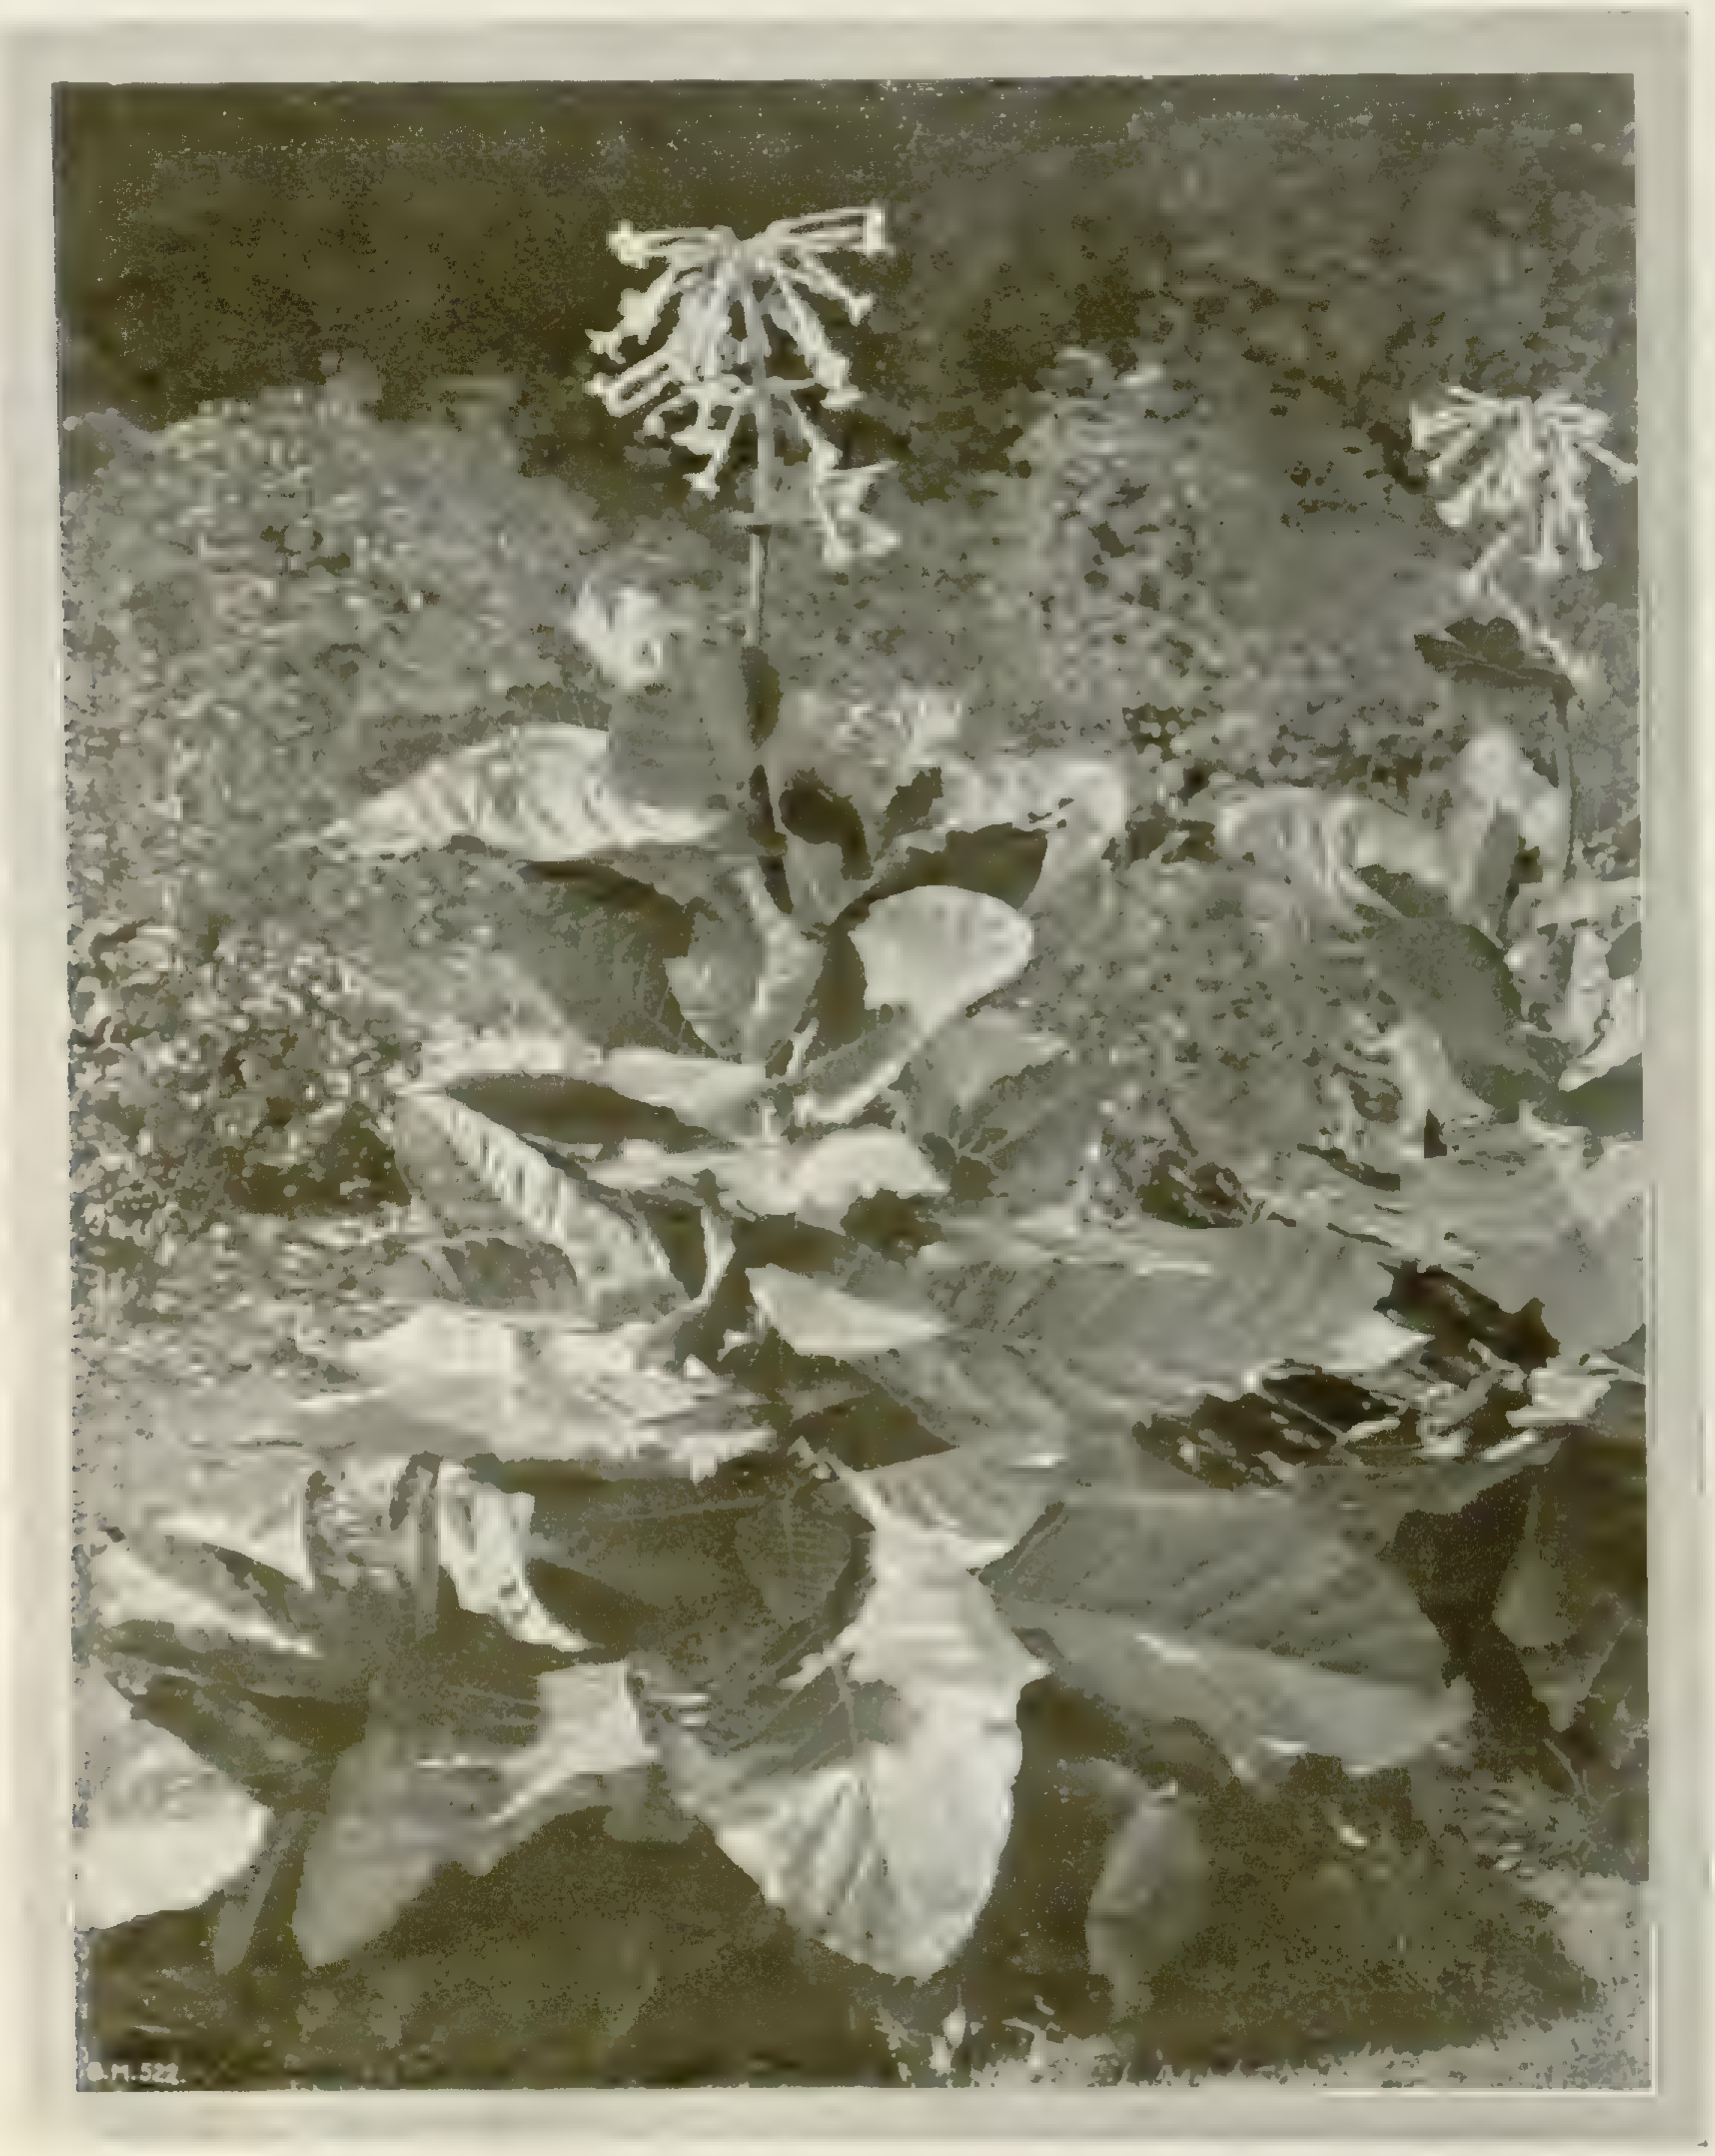
I think we do not use the rose enough in the form of hedges. Many varieties lend themselves far better to this style of culture than a large number of the plants that are often utilised for it. If we want a hedge for effect, for protection, or for dividing the garden, we can select suitable varieties.

One of the most impregnable hedges we could possibly have can be quickly built up of Penzance briars, Rugosas, and such of the polyanthas as Queen Alexandra, Psyche, Blush Rambler, and a few more. True, these take up a little more space than the ordinary quickset and privet, but they are infinitely more beautiful, grow quicker, and are no more trouble to keep within bounds. One most essential point is to keep to one style of growth throughout the length of hedge, even though more than one variety of rose is to be used. Blush Rambler and Queen Alexandra go well together, but it would not be advisable to put Dorothy Perkins, Lady Gay, or Hiawatha with them, because the last-named have a tendency to ramble wider and keep to the ground line unless some other means of support are employed. Still, this latter class of rose makes a grand hedge if we can supply a few strong stakes and wires to keep them a little within bounds, and in this case I should prefer a double row of supports. There is not so much difficulty in pruning these roses as one might at first imagine. It is simply a matter of removing the greater portion of dead or exhausted wood. There will always be plenty of good shoots coming out from the sides and top that may be tied to, or pulled under, the supporting wires, and the looser they are within reason the more effectual the hedge will be.

Where there is ample room few things are more showy and bold than a hedge of these roses. They are among our earliest bloomers, and after making a gorgeous show from four to six weeks, they still carry good foliage that is seldom affected by mildew or red rust, and the majority of them are almost evergreen. This class of rose will provide a hedge 6ft. to 10ft. high, and may be from 3ft. to 5ft. through. For a hedge of 3ft. to 5ft. in height we can do better by selecting the rugosas and similar growers; Fellenberg among the hybrid Chinas, for example, or Mrs. Bosanquet from the hybrid Bourbons.

One of the prettiest hedges I have seen was made up with Gruss an Teplitz, and this rose can scarcely be put to more effective use. In this instance the pruning was done with the hedge-shears (?) similar to an ordinary hedge; the resulting growth soon broke up any undue formality, and throughout the season it was a glow of colour and handsome foliage. From the dwarf polyanthas, of which Maman Levavasseur, Mrs. Cutbush, Flocon de Neige, and Madame N. Levavasseur are examples, we can have hedges from 18in. to 2ft. high. If care is taken to select free and fairly erect growing varieties we can secure any intermediate height up to the extreme reached by the Penzance briars. Even the common sweet briar is not used so much as it deserves, and this can be clipped to any size and is always pleasing, more especially after a summer shower, when the fragrance of the leaves is very pronounced.

A. PIPER.



NICOTIANA SYLVESTRIS IN A BRENTWOOD GARDEN.

ORNAMENTAL TOBACCOS.

Among the nicotianas there are a few varieties which make splendid subjects for that class of gardening usually known as sub-tropical. Most of them are very quick in growth, have large leaves, and produce a tropical-like effect, which gives an air of grandeur to the garden when they are well placed either as "dot" plants or in the centres of large beds. They are also very striking when in association with other sub-tropical plants, such as the ricinus, wigandias, the larger-leaved solanums, and others of that class. In their use the matter of effective grouping should meet with full consideration, and if this is well carried out there can be no question as to their decorative value.

These tobaccos are easily grown, and should be raised from seeds sown in March or early in April, and grown on quickly without a check, and in rich soil, until, say, the end of May, when they should be planted out in a deep soil rich in humus, and with a liberal quantity of well-decayed manure. It is important they should be induced to grow quickly to their fullest possible size, for if they are allowed to become stunted or puny their great attraction is considerably minimised. With a view to the best development a sheltered and warm position should be selected, for shelter and warmth tend to quick growth, and in addition prevent the leaves being injured, as they certainly would be if exposed to any rough winds. The old N. wigandoides is not now so often seen as it was formerly, but it is a noble plant, with broad, woolly leaves of erect habit. It grows six feet high in the season, and being of a shrubby habit it could be kept over the winter in the greenhouse, though this is hardly worth while in an ordinary way, as the plant loses much of its attractiveness when allowed to branch. N. colossea is a very noble form, the young leaves are very effectively tinted with red, it grows with great freedom when well planted, and its leaves reach at least two feet in length by one foot in breadth. If this can be given proper attention, and pot or box room, seeds should be sown in heat as early as February, and it will repay the extra trouble. N. tabacum macrophylla, or macrophylla gigantea, is a handsome plant with bread leaves, and reaching a height of six feet, the plants being crowned in season with rosy-red flowers.

Newer than any of the foregoing is N. sylvestris, the subject of the accompanying illustration; this has the double merit of bold, handsome, large leaves, and a free-flowering habit well shown in the illustration. It is certainly one of the best of the tobaccos, and its chaste white and sweet-scented flowers are very attractive when surmounting a well-grown specimen. Like all tobaccos grown for their flowers, this should be grown where shaded from the midday sun, for though it does not close its flowers quite so readily under full light, as does N. affinis and its varieties, it has a tendency that way, and does not look its best in bright weather under the direct rays of the sun.

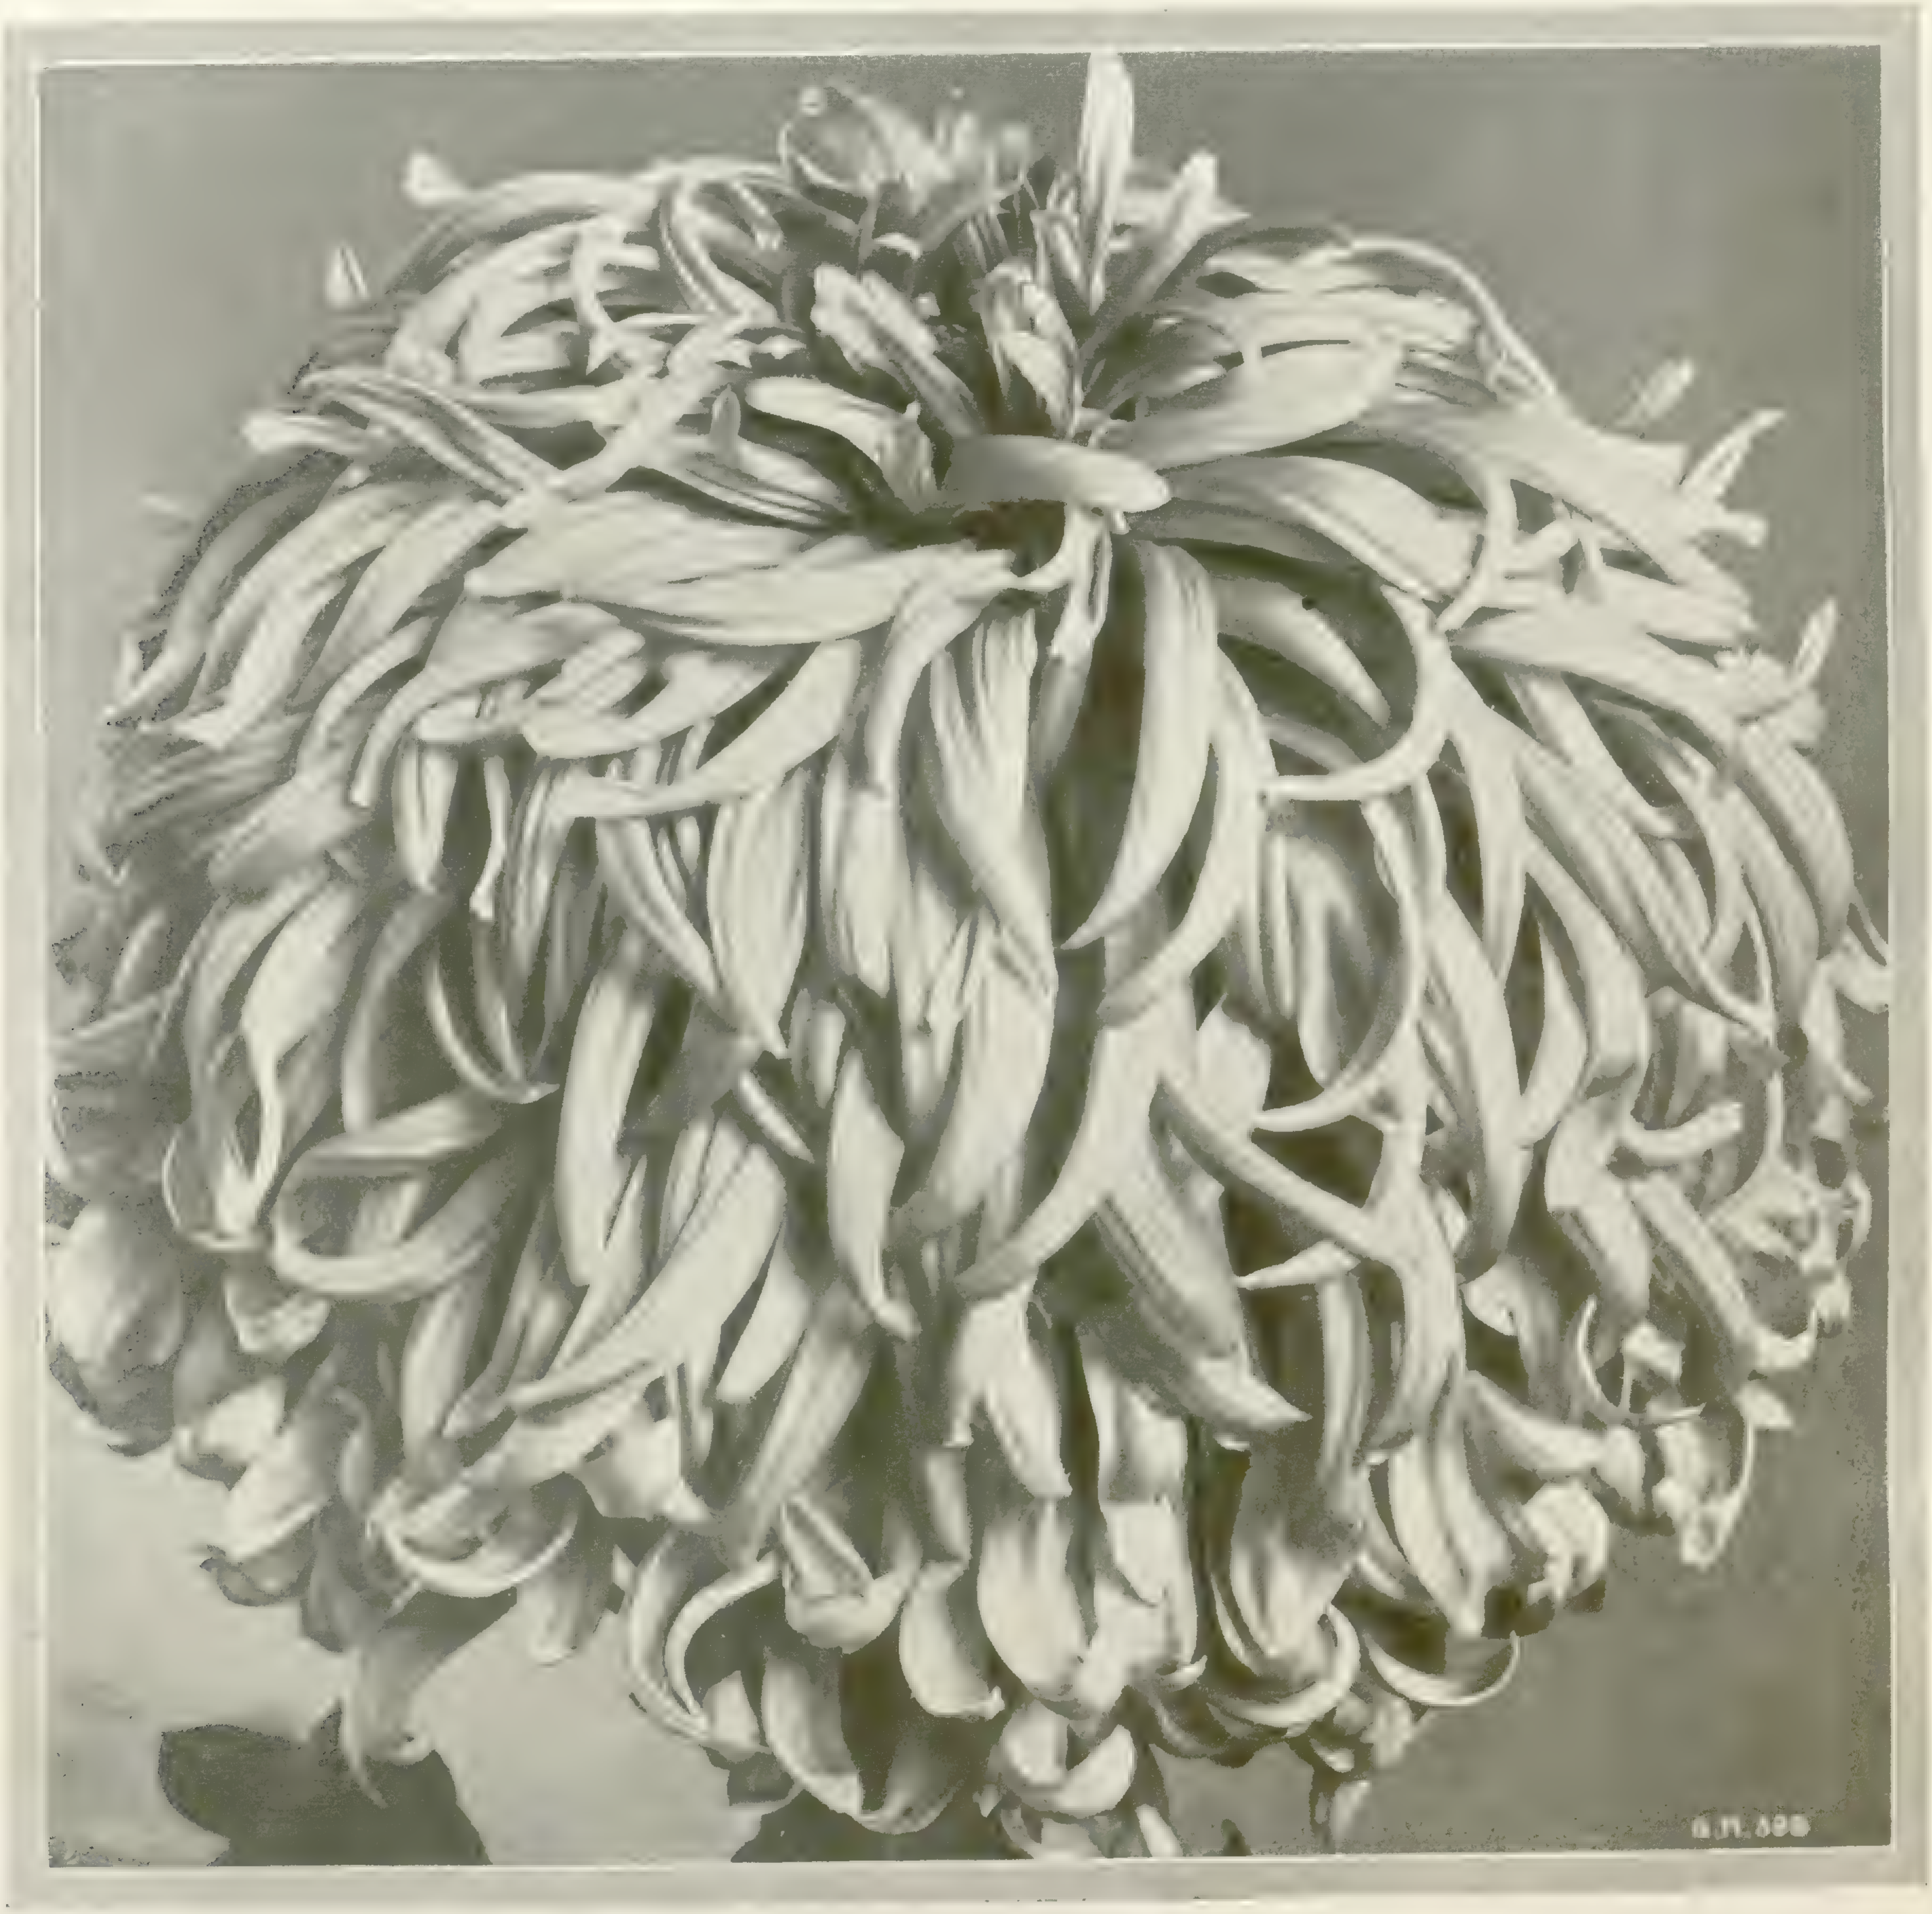
Shipley Hall Gardens.

A BEAUTIFUL CHRYSANTHEMUM.

Although the advances made in the varieties belonging to the Japanese section of the chrysanthemum are not at the present time so marked as they were from ten to twenty years ago, there can be no question as to good progress being still made in the work of improvement. The high state of development to which those varieties have been brought, as the result of the strenuous and well-directed efforts of raisers, has very naturally made growers more exacting in their requirements, and less ready to become enthusiastic over novelties. Each year varieties more or less meritorious are introduced, and it cultivators do not become enthusiastic over them they are not less ready to show their appreciation of improved forms than they were in bygone years, as evidenced by the rapidity with which blooms make their appearance in exhibition stands. The extremely beautiful variety, Edith Jameson, of which an illustration is given herewith, is a case in point. Blooms were shown by Mr. Norman Davis, of Framfield, by whom it was introduced, at one of the meetings of the Royal Horticultural Society held in the autumn of 1907, and the Floral Committee unanimously made an Award of Merit in its favour. They also received a full share of attention from the many visitors to the meeting, and the variety was reported upon in these pages, and described as one of the very finest flowers of its season. There were, however, no enthusiastic references to it by growers in the Press, yet it would appear that they were not slow to add it to their collections, for last autumn we met with it in many winning stands in various parts of the country. The high opinion we formed of the variety when we first saw it has been amply confirmed by the results obtained in the chrysanthemum season of last year. There is no occasion to suggest comparison with other varieties introduced in the same season by describing Edith Jameson as the best variety of the year, but it may be said that it is one of the most beautiful of the Japanese chrysanthemums, and that it has no equal in its attractive shade of colour, which may be described as a rich magenta-purple.



JAPANESE CHRYSANTHEMUM, EDITH JAMESON.
Introduced by Mr. Norman Davis; the flowers are very large, and the colour magenta purple.

CIDERLAND.

From time immemorial cider has been the standard beverage in the West Country, and every farm in the apple-growing districts has its orchard attached, in which the fruit is grown for making the family drink. For the most part the trees are old, and consist of varieties of doubtful origin, considering that when many of the ancient orchards were established, the method of propagating was that of sowing the seeds of the apples as they came from the mill, and growing the seedlings until they eventually became trees and bore fruit. Some of these varieties enjoy local reputation for making good cider, and for the most part they bear the names of the person on whose farm they were raised, while other varieties are of little or no value whatever, but for some reason which it is difficult to explain they have been allowed to remain, perhaps because the West Country farmer works on the principle that all is grist that comes to the mill.

It would be hardly correct to say that the major portion of the trees in West Country orchards are grown or ever have been, but on the other hand they have grown themselves, with little or no care or attention, since they were planted simply because Dame Nature has adapted the soil and situation to them. One wonders what the wealth of the West Country in apple production might have been had the trees been given the care and attention they receive, say, on the other side of the Atlantic, but that is part of another story, and I am dealing with the orchards as they are. From the point of view of an up-to-date fruit-grower, a typical West Country cider orchard provides material for criticism and ridicule. The thick, over-crowded trees, the congested heads, and moss-covered limbs are pointed to as illustrations of how fruit trees should not be grown, and the way they are stuck about in the orchard gives one the impression that they were never planted, but grew there of their own free will.

The artist looks at the trees with other eyes, the gnarled, twisted stems and the want of order appeal to him, while the mistletoe which grows in the branches is to him charming. Of course, you cannot expect the artist to see with a fruit expert's vision, and, however much West Country orchards may be open to the criticisms of the latter, they have served the purpose of models for some of the most beautiful pictures ever hung. As for the farmer, it is not usual for him to look upon the orchard with the eye of either fruit expert or artist. He realises, perhaps, that the orchard is not what it ought to be, but there it is, and was much the same in his father's day, and it serves the purpose of providing apples for filling the cider casks with liquor. If the crop fails one year he does not trouble to look into the causes, for the simple reason that there always were failures, and he expects there always will be, while if he gets a bountiful return of fruit he fills his casks with cider and is thankful. As for the mistletoe, well, it may be a parasite, and is perhaps harmful, but it seems to take a lot of it to kill an apple tree, so he leaves it alone, unless he can, by cutting it turn it into money at Christmas time. There are a few, indeed, who say that they make more of the mistletoe in the orchard than of the apples, and considering the character of some of the latter one can quite believe it.

In the spring when the trees are in bloom the old orchards are delightfully beautiful, what with the pink blossoms overhead and the flowers that spring up in the grass beneath, and the orchard presents another picture when the fruits turn their rosy cheeks to be kissed by the sun. As autumn comes on, and the yellow leaves flicker mournfully to the ground, you see waggons drawn up under the trees, and it is a standing job to pick up the fruit as it falls, and put it into the vehicle to be drawn to the cider house ready for the grinding. Want of care and cleanliness in dealing with the fruit is often urged against the local cider maker, and not in many cases, I fear, without cause, and the liquor produced tells the tale. In the old days cider-making was a stock job through the winter, like threshing with a flail, but that was when all the juice was squeezed out of the apples under stone rollers that were pulled slowly round by a horse hitched to a shaft outside the shed. In a good many establishments the grinding is still done in the old stone mill, but in others the ancient apparatus has given place to the modern cider mill, made of machinery which tears the fruit to pieces and extracts the juice in much less time. In his cider-making, as in other operations, the farmer to-day has to reduce the labour as much as possible, and consequently he employs the modern mill, which goes round the country grinding as the itinerant threshing machine does for threshing, but there are some of the old-fashioned people who contend that there is no cider like that pressed out under the ancient stone roller. I think their days are numbered, however, and old cider troughs are much in demand as ornaments in flower gardens, so they will be handed down to posterity as relics of customs past.

There is cider and cider in the farmhouse cellars in the West Country, some quite pleasant and palatable, and some that only an educated cider drinker could quaff with relish. As a rule, the cider on the household table is not quite the same as the cider for the men, but the latter must be wholesome if the sturdy frames and healthy-looking faces of the West Country labourers are anything to go by. It is customary in the West for the labourers to receive so much cider a day, and wherever the latter are at work, be it hay-making in the heat of the summer or ploughing on the coldest day in winter, the little wooden keg containing the liquor goes with them, and, if accounts be true, the power of the beverage to cool the human body in the summer and warm it in the winter must be wonderful. There is one thing certain, that of all the alcoholic beverages made, there is none more wholesome than cider.

To-day there is a strong movement on foot to popularise cider as a national drink. Whether it will succeed remains to be proved, but the National Fruit and Cider Institute at Bristol, which is maintained by the Board of Agriculture, the Bath and West Society, and the County Councils of Devon, Somerset, Gloucester, Hereford, Monmouth, and Worcester, is being used as a means to the above end. The Institute realises that if good cider is to be made in the future good varieties of cider apples must be planted, and this year some hundreds of trees are being distributed in the adjoining counties for the purpose of establishing experimental cider orchards. There is little fear of cider-making being discontinued on farms for domestic purposes, but it is thought by some authorities that cider as a commercial beverage will be factory-made, because the best appliances cannot be kept on every homestead, and that the part of the farmer will be to grow apples for the maker.

Years ago when the majority of West Country orchards were established, almost the only use for apples was for cider-making, but now there is a demand for table fruit as well. This demand has led to the planting of culinary and dessert apples, somewhat to the neglect of vintage fruit, and most of the cider apples, as well as the majority of the perry pears, come from old trees, and perhaps the finest old specimens of the latter in the country are to be seen in the county of Hereford. It would be fatal to the interests of the cider industry to stop planting vintage fruits, because the old trees, in spite of their tenacity, cannot go on for ever, and it is a pity that more than one good old local cider apple has dropped out of cultivation with the death of the trees that grew them. It is hoped, therefore, that the cider makers of this generation will realise that there is another to follow them, and to remember that if their forebears had not planted there would be no apples to grind now for filling the cider casks. G. H. H.

PROFITABLE FRUIT GROWING for Cottagers and Small Holders of Land.—By John Wright, V.M.H. A Gold Medal Essay, written for the Worshipful Company of Fruiterers. Fully illustrated. Price 1s., by post 1s. 3d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

BLACKBERRIES AND LOGANBERRIES.

The merits of these fruits are not nearly so much appreciated as they deserve. Few people seem to know what the loganberry is, and when you talk about blackberries so many persons seem to think one is alluding to the wild blackberries of the hedges. To America belongs the credit of introducing the blackberry as a cultivated fruit and the loganberry also. Both require the same treatment, and this is quite of a simple character, very much resembling that needed for raspberries, but they may be made a more ornamental feature in the garden. A very pretty archway can be made with blackberries over a path in the kitchen or fruit garden, or they can be trained in pergola fashion. Wire arches are easily fixed over a path, and may be of any width, and 7 or 8ft. high in the centre and 2ft. apart. Or a more continuous arrangement can be made by placing the arches 12in. apart. The former distance is the better, as more space is provided for the plants, and the many sucker-like growths springing from the base of each clump are stouter.

To obtain the fullest crops from both of these fruits liberal treatment is an absolute necessity, as vigorous growths are required annually to cover the space allotted, and produce fruit of large size and high quality. Deeply trenched and heavily manured soil is the first consideration, in the same way that early autumn planting affords an opportunity for the plants to make satisfactory progress the first season. Instead of attempting to obtain a crop of fruit the first season after planting, it is better to cut the canes back to within six inches of the soil and thus encourage them to make strong shoots in the following season, as from these heavier crops the next and subsequent years will be obtained. Weakly growths are of little value as they produce small fruits and a light crop.

Should the first summer be a dry one abundance of water to the roots and copious syringing of the foliage after hot days will do much toward encouraging freedom of growth. The annual pruning should be done directly the fruit is gathered by cutting away all the old fruiting canes and making space for the suckerlike growths of the current year. By pruning thus early the latter have a much better opportunity for attaining full development and maturity, and, as a consequence, give a more satisfactory crop the following year. In training the shoots over the arches it is desirable to keep them thin, so that they are not so crowded as to deprive each other of the needful light and space. The following year the shoots pushing from these stout growths which give the clusters of fruit will hang mainly downwards with the weight of their fruit, and under the arches have a very pretty effect. As blackberries are gross feeders, heavy mulchings of half decayed horse manure will do much towards assisting the fruit to swell to its fullest size, and develop its full flavour. When these berries are thoroughly established manure should be annually added to the soil to maintain a vigorous growth, and copious supplies of liquid manure should be given when the fruit sprays are growing from the main rods, and when the berries are approaching the ripening stage. As to variety there is not much to say about this. Laciniatus, or parsley-leaved, an English-raised variety, is quite the best of the cultivated blackberries. Wilson Junior is the best of the American blackberries for culture in this country. S. H. P.

GREENHOUSE CYTISUS.

Among shrubs that delight us with their flowers in the greenhouse during spring, few are more welcome than those species of cytisus generally regarded as too tender for the open air, so that unless in favoured districts, glass protection becomes necessary in winter; nor is this regrettable, for being singularly amenable to pot culture they have for long been grown under this system, and it is probable that few subjects give anything like an equal return for the small amount of labour or expense that their cultivation entails.

The species of cytisus generally favoured are, for the most part, natives of Teneriffe and the Canary Islands. With rare exceptions they produce yellow flowers, borne upon the terminal and lateral branches in the form of light and graceful racemes; the flowers are often sweetly scented, and the foliage is trifoliate in every instance.

The best and oldest cytisuses are C. canariensis, which has comparatively large and effective foliage; to some extent this is surpassed in the variety Everestianus, which has deeper-coloured flowers; and Attleanus, racemosa, and the variety elegans have smaller leaves. Although all have yellow flowers yet their relative size and varied disposition imparts a seeming individuality to each, which renders them more or less distinct. With gentle forcing the flowering season begins in February, and can readily be prolonged into May by growing a percentage of the plants cool, while a late-flowering species, like C. canariensis, can be profitably employed to this end. A very old favourite, and at one time very popular, is the white-flowered Cytisus fragrans, a species having very fragrant flowers.

The propagation of these brooms is effected in spring either by seed, which germinates readily in heat, or by cuttings of the young growths inserted in pots of sandy soil and placed upon a gentle hotbed. After the cuttings are rooted they are potted singly, and grown in an intermediate house until June, when they are plunged out of doors for the summer, which induces a short, sturdy growth, and also materially influences the ripening of the shoots, so that a free and more abundant harvest of flowers naturally follows. The growing season is generally complete by September, and about this date the plants are removed to a cool frost-proof frame or orchard house. Water must be sparingly applied, as anything approaching saturation at this period proves fatal.

Old plants after flowering should have the shoots pruned back, placing the plants in a warm, moist house to induce the new growth to break regularly, and at this stage any repotting necessary should be performed.

The soil should consist of good loam, with plenty of grit or sharp sand added, and an efficient drainage should be provided. Artificial manures are seldom necessary while the plants are young, but old specimens are benefited by the judicious use of some approved fertiliser in the potting compost. Liquid manure can generally be used to advantage if supplied previous to the opening of the flowers.

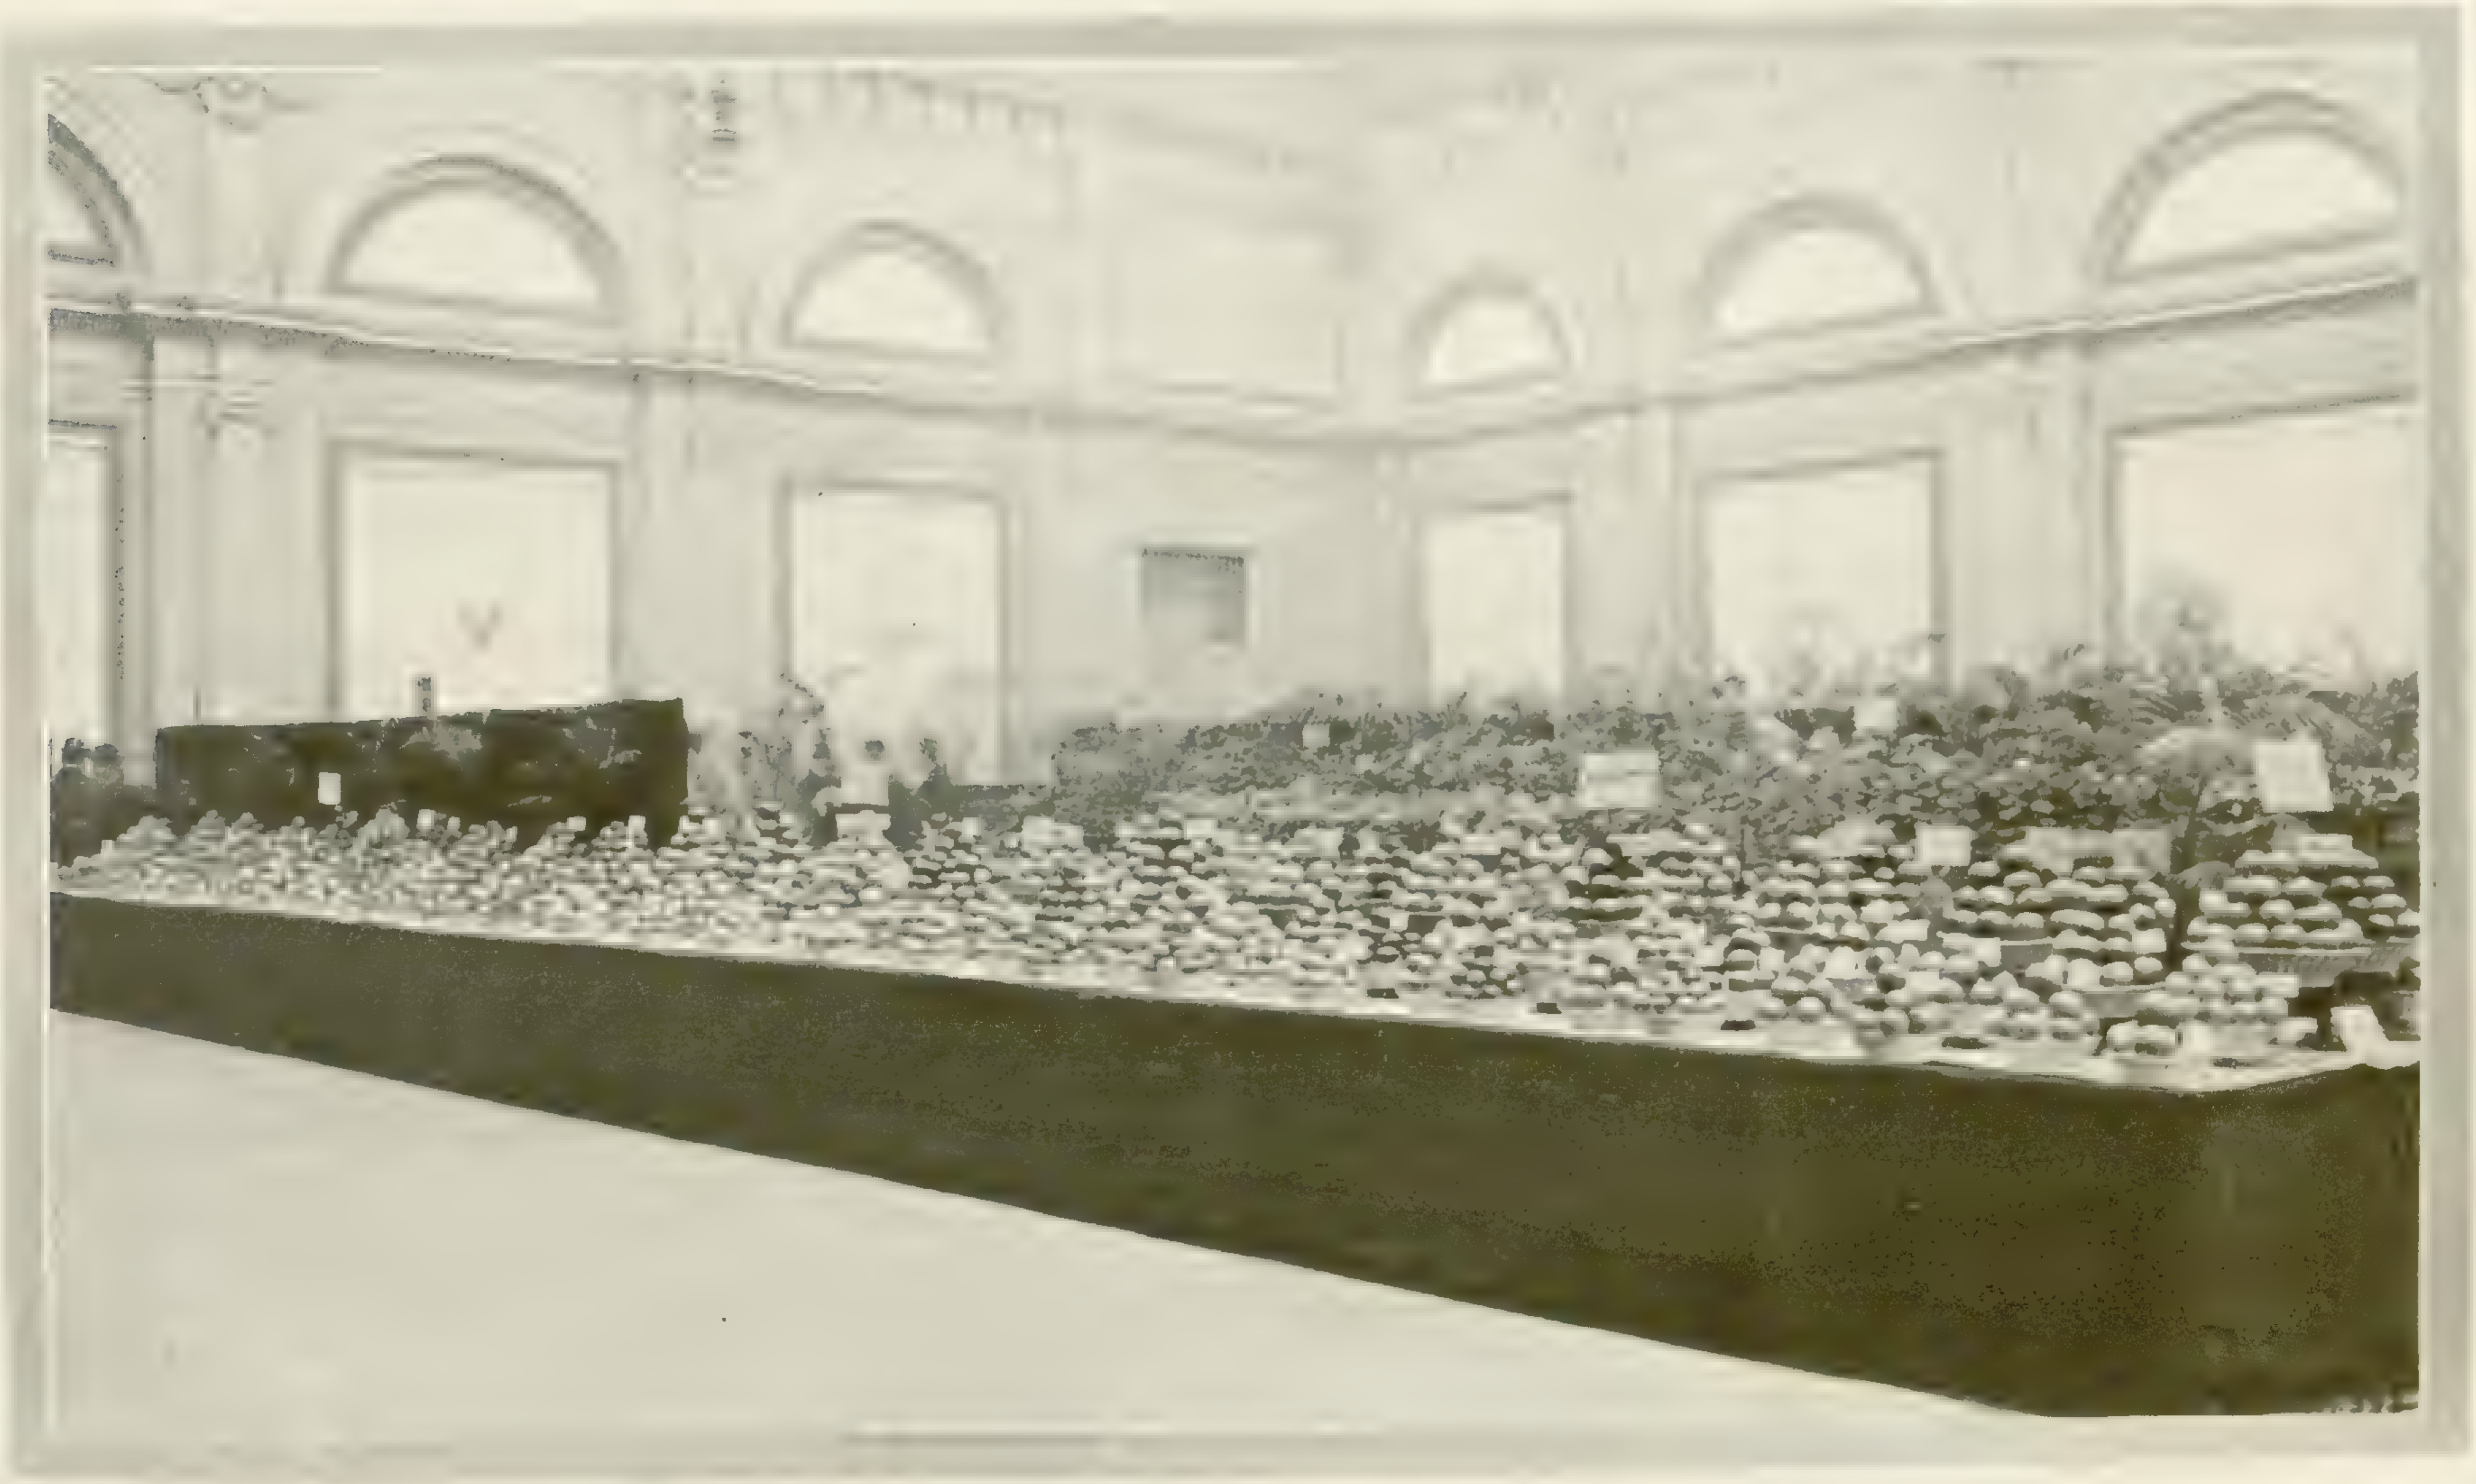
Greenhouse cytisuses lend themselves to training into various forms, such as pyramids and standards. Young plants should be selected, and the main shoot run up to the required height, then, by pinching out the points of the laterals the necessary shape is obtained. Several years will be required to develop large specimens. Small examples adapted for table or room decoration are grown from cuttings rooted in the spring of the previous year. These will require pots five inches in diameter, and they should be allowed to run up from 24 to 30 inches in height, and by systematic pinching have the diameter kept in proportion to the height.

Thomas Smith.

Walmsgate Gardens, Louth.

A NOTEWORTHY COLLECTION OF APPLES.

As stated on page 969 of last year's volume of the Gardeners' Magazine, Messrs. James Veitch and Sons, of Chelsea, contributed to the second of the two meetings held by the Royal Horticultural Society in December last a collection of apples that, by reason of its comprehensiveness and remarkable excellence attracted much attention. In the collection were represented one hundred and fifty varieties, and the fruits were, without exception, of the largest size, splendidly coloured, finely finished, and in a high state of preservation. While appreciating, as in the case of other visitors, the attractiveness of this immense display of apples, it appealed to us the most strongly as a demonstration of the possibilities of keeping apples in excellent condition for a considerably longer period than is by many considered practicable. In many gardens it would not be possible to have some of the varieties included in the collection in a good state of preservation at the end of December, because of the structures provided for the storage of apples falling short in one or more of their details. A cool, equable temperature, and an atmosphere free from excessive dryness are two conditions essential to the perfect keeping of apples and pears, and these have been fully complied with in the fruit room which Messrs. Veitch have had in use for some years past in their Langley nurseries, which are now the headquarters of their fruit department. This structure is one that might be imitated on a smaller scale in private gardens, where fruit culture is carried out on a comparatively large scale, as it is important apples and pears should be had in good condition for as long a period as possible. Messrs. J. Veitch and Sons were, we would add, awarded by the Royal Horticultural Society a gold medal for this fine collection.



THE REMARKABLY FINE COLLECTION OF APPLES

For which Messrs. J. Veitch and Sons were awarded the Gold Medal of the Royal Horticultural Society at the meeting held December 22, 1908.

LATE SINGLE CHRYSANTHEMUMS.

(Concluded from p. 14.)

Selection of Varieties.

From the many late-flowering singles, it so difficult to make a limited selection. The following, however, are worthy of a place in every collection: Framfield Beauty is indeed a beauty, bearing large, deep, rich velvety crimson flowers of good form. J. F. McLeod is a variety but little known, but valued for its large golden-yellow blossoms, that are borne in lovely sprays. A variety with flowers of medium size is J. T. Angus. In this case the colour is rosy-cerise, and it is one of the best of this colour in the late kinds. A beauty for Christmas displays is Hilda, the colour being a warm orange terra-cotta. A variety that is worthy of inclusion in the smallest collections is Framfield White. The blossoms are of the purest white, and are borne on stiff, erect sprays. Either partially or severely disbudded, this is a chaste and beautiful late kind. A very late kind is Robert Morgan; the flowers are large, and of pleasing form, and their colour is an intense rosy-amaranth. A good bush plant is a chestnut-coloured variety named Mrs. Baillie, which in December is usually in good form; the habit is dwarf. A charming pink is Lorna Dando; under careful treatment its blossoms may be gathered at Christmas. Edgar Forbes is another fine flower, the colour being a shade of rosy-mauve on white ground. Cannell's Gem is a beautiful flower of a rich rosy-amaranth colour, and the dwarf plants are at their best in December.

Those who have a preference for flowers with large flat florets will find their needs supplied in Wyndham. This is a beauty, and the flowers are pure white. A dainty sort is seen in the blossoms of Mrs. Norris. The colour is yellow. In Lady Windsor we have a variety producing large flowers of deep rosy-lilac, with white centre, and in Golden Star a variety with clear yellow blossoms and greenish disc. What some growers regard as a single of poinsettia-like form is Dorothy Fortescue. It is a pure white flower of large size, and is beautiful for late use. For years the cerise-pink blossoms of Mrs. D. B. Crane have been useful for December displays, and they are still valued, although the variety has been in commerce a long time. Lovely sprays of reddish terra-cotta flowers are seen in Nora Davies, a reliable variety for fairly late use, and in the spidery blossoms with tubular florets of Thirza Cherry, we have decorative material of the very best; the colour is a shade of soft mauve.

A few good new things are Aurora Boreale, orange-shaded crimson; Cloth of Gold, old gold; Ursa Major, pink, with white zone round yellow disc; and a grand trio of yellow varieties, named respectively, Pollux, Juno, and Perseus, combining richness of colour and vigour of constitution. Doreen, deep yellow; Annie Farrant, rich crimson; Cannell's White; G. W. Forbes, crimson, shaded amaranth; Jack Lay, buff-yellow shaded red; and Edith Pagram, were some of the better varieties at the December show of the National Chrysanthemum Society.

Highgate. D. B. Crane.

The Midland Carnation Society's Show will be held in the Botanic Gardens, Edgbaston, on Wednesday and Thursday, July 28 and 29 next.

ALPINE FLOWERS AT HOME.

While England was having a beautiful summer, Switzerland experienced one of the worst for fifty years. Three really fine days together were quite rare last season, but on September 17 a spell of beautiful weather set in which lasted till October 19, when a little rain fell. Two days later at Lucerne it was as cold as in December, the thermometer registering only 2 degrees Cent., such cold not having been felt in October for ten years. It was all the more uncomfortable as it followed several weeks of such unusually warm weather. A sea of mist covered Switzerland from the Alps to the Jura, so that to obtain sunshine it was necessary to ascend to about 1,400 metres, where the sky was blue and clear.

One of the worst features of the summer weather in 1908 was the gales, and the very sudden way in which they would spring up. In August much damage was done to fruit and other trees in the Rhone valley, but in the mountains very few firs, pines, or larches were blown down, notwithstanding the terrible storms; for their strong horizontal roots penetrate such long distances even on the poorest and rockiest of soils. Far more trees in the Alps are destroyed by avalanches of snow in the spring than by gales.

As late as the middle of May there was a foot of snow at Brigue in the Rhone Valley, and the cold and wet summer had the effect of keeping back some of the Alpine plants; so that during a few sunny days in the second week of September, when I did the so-called "Tour du Mont Blanc," a magnificent walk around the whole range of Mont Blanc, which better than anything else gives one an idea of the huge extent of this massif and of its innumerable peaks and glaciers—many alpine plants were in bloom. These included several gentians, campanulas, and saxifrages; rampions, hedysarums, elegant erigerons, Alpine asters, handsome Carline thistles, and other composites, and these were decorating some of the Italian passes as one is accustomed to see them in July and August. Yet on September 12 at 7 a.m., hoar frost covered the vegetation in the Italian Val Ferret above Courmayeur, as low as 5,000ft., and before the top of the Col de Ferret was reached the snow was driving fitfully across from the Grandes Jorasses, and battling with the sun for supremacy. Alpine plants seem inured to violent climatic idiosyncrasies, and perhaps it is that they owe much of the brilliance and purity of their flowers to this trait.

In the Swiss Val Ferret the fine sweep of pastures above Pras de Fort, which in July were a mass of gorgeous flowers with Lilium Martagon, deep blue campanulas, and the handsome Astrantia major predominating, had not given their usual second crop of grass, and they looked as if they had been mown the previous week, whereas in reality the grass was cut the first week in August. The villagers had never known such a cold and wet summer.

On arriving at Lac Champex on September 13, the ground was white with snow, and never before in the knowledge of the people had snow fallen in the middle of September. Next morning it was still snowing, but in the afternoon I ventured to resume my journey over the mountains to the Col de la Forclaz, the starting-point of the tour. The snow was rapidly melting, though the pines on the higher slopes were prettily wreathed in white. The clanging bells of cattle in the distance were heard, and soon the cows were met on their tortuous downward march from the "alp" called Bovine, where they had spent a short and cold three months.

Then at 6,500ft. above the sea ripe raspberries and a few lingering strawberries were gathered amidst the melting snow. Bilberries, so common in this part of Switzerland, were abundant everywhere, and at that time of year their foliage—from a deep orange to a bright crimson—gives an unusual richness of colour to many a mountain side.

Autumn visitors to the Alps, at any rate, have the pleasure of seeing innumerable shrubs and trees in fruit. And in September there is a crispness in the air and a transparency in the atmosphere that is rare in the height of summer; so that the effect of distance and mid-distance is never so beautiful; the rocky hills are rarely so blue in summer, nor are the mountain tops so pure a pink as when lit up by an evening glow in autumn.

Nowhere are berries of all kinds more abundant than in the Trient valley. The berberis early in September is a deep brick-red in the warmer spots, and higher up the berries vary from light green and yellow to the deepest orange. Wild raspberries, as fine and as fully flavoured as those in gardens, are so abundant that they are served for dessert in the hotels. Red currants, which grow on bushes larger than those at home, are left for the birds. In dry places in woods and on heaths the brilliant scarlet berries of the dwarf cowberry (Vaccinium vitis idœa) attracts the eye, and it forms as beautiful an object in autumn as its pale pink waxlike blossoms do in summer, and it should be more frequently cultivated. The roots of this plant sometimes penetrate enormous distances, and occasionally it is found growing in decaying wood between the bark and the main portion of the trunk of a tree. The coral-red bunches of fruit of the mountain elder adorn many a gloomy glen, and this shrub often grows in just the places where the Wych elm is found native, but perhaps at a slightly higher elevation.

Purple and nearly black berries are as common as red in the Alps, but the Stone bramble (Rubus saxatilis), with its transparent red drupes as large as red currants, is the only bramble frequently found high up in the Swiss Alps, except occasionally in warmer spots the pretty Rubus tomentosus, a bramble with greenish-white flowers and leaves with a thick whitish felt beneath. This blackberry is not found in the British Isles, though its distribution further south is so extensive.

A Cornish correspondent speaks of the thermometer being 79 degrees Fahr. on October 2. It can hardly have been less that day, and for several subsequent days in some of the Swiss mountains. That morning I was crossing the famous Joch Pass from Engelberg to Meiringen, and the weather was so warm and so absolutely still that on arriving at the deep blue Engstlensee, more than 6,000ft. above the sea, I had a brief, but very brief, dip in its crystal waters, though the lake is fed from a glacier not far off. Some years ago this lake was stocked with Canadian trout, and they seem to thrive, notwithstanding the altitude, the stony bottom, bare of algæ, etc., and the dearth of vegetation suitable for the growth of larvæ; for some trout of three and five pounds were caught last summer. Perhaps, like Alpine plants they have a knack of adapting themselves to their environment.

On October 13 I was collecting roots of Alpines for a friend, and even so late in the season Gentiana asclepiadea and G. ciliata were in bloom. Both these handsome species might be more cultivated in

England, and particularly as they are the latest of all the Alpine gentians to blossom, G. ciliata never being seen in flower until the middle of August. It delights in shaley banks without much other vegetation, but is also seen in pastures on a limestone soil. It is, however, a difficult plant to get up, for the stem easily breaks off from the small delicate root. G. asclepiadea, on the contrary, has a long, thick taproot. That day the white flowers of Ranunculus alpestris were still adorning a desolate waste, and on a limestone rock hard by was a plant of the rare Delphinium elatum at the most unusual height of about 6,000ft.

Stray flowers of Gentiana verna are frequently seen late in autumn, and last October I had the pleasure of seeing quite a second harvest of G. bavarica in two swampy places. In June I came upon a large area of G. bavarica with violet flowers, which variety does not appear to have been recorded before.

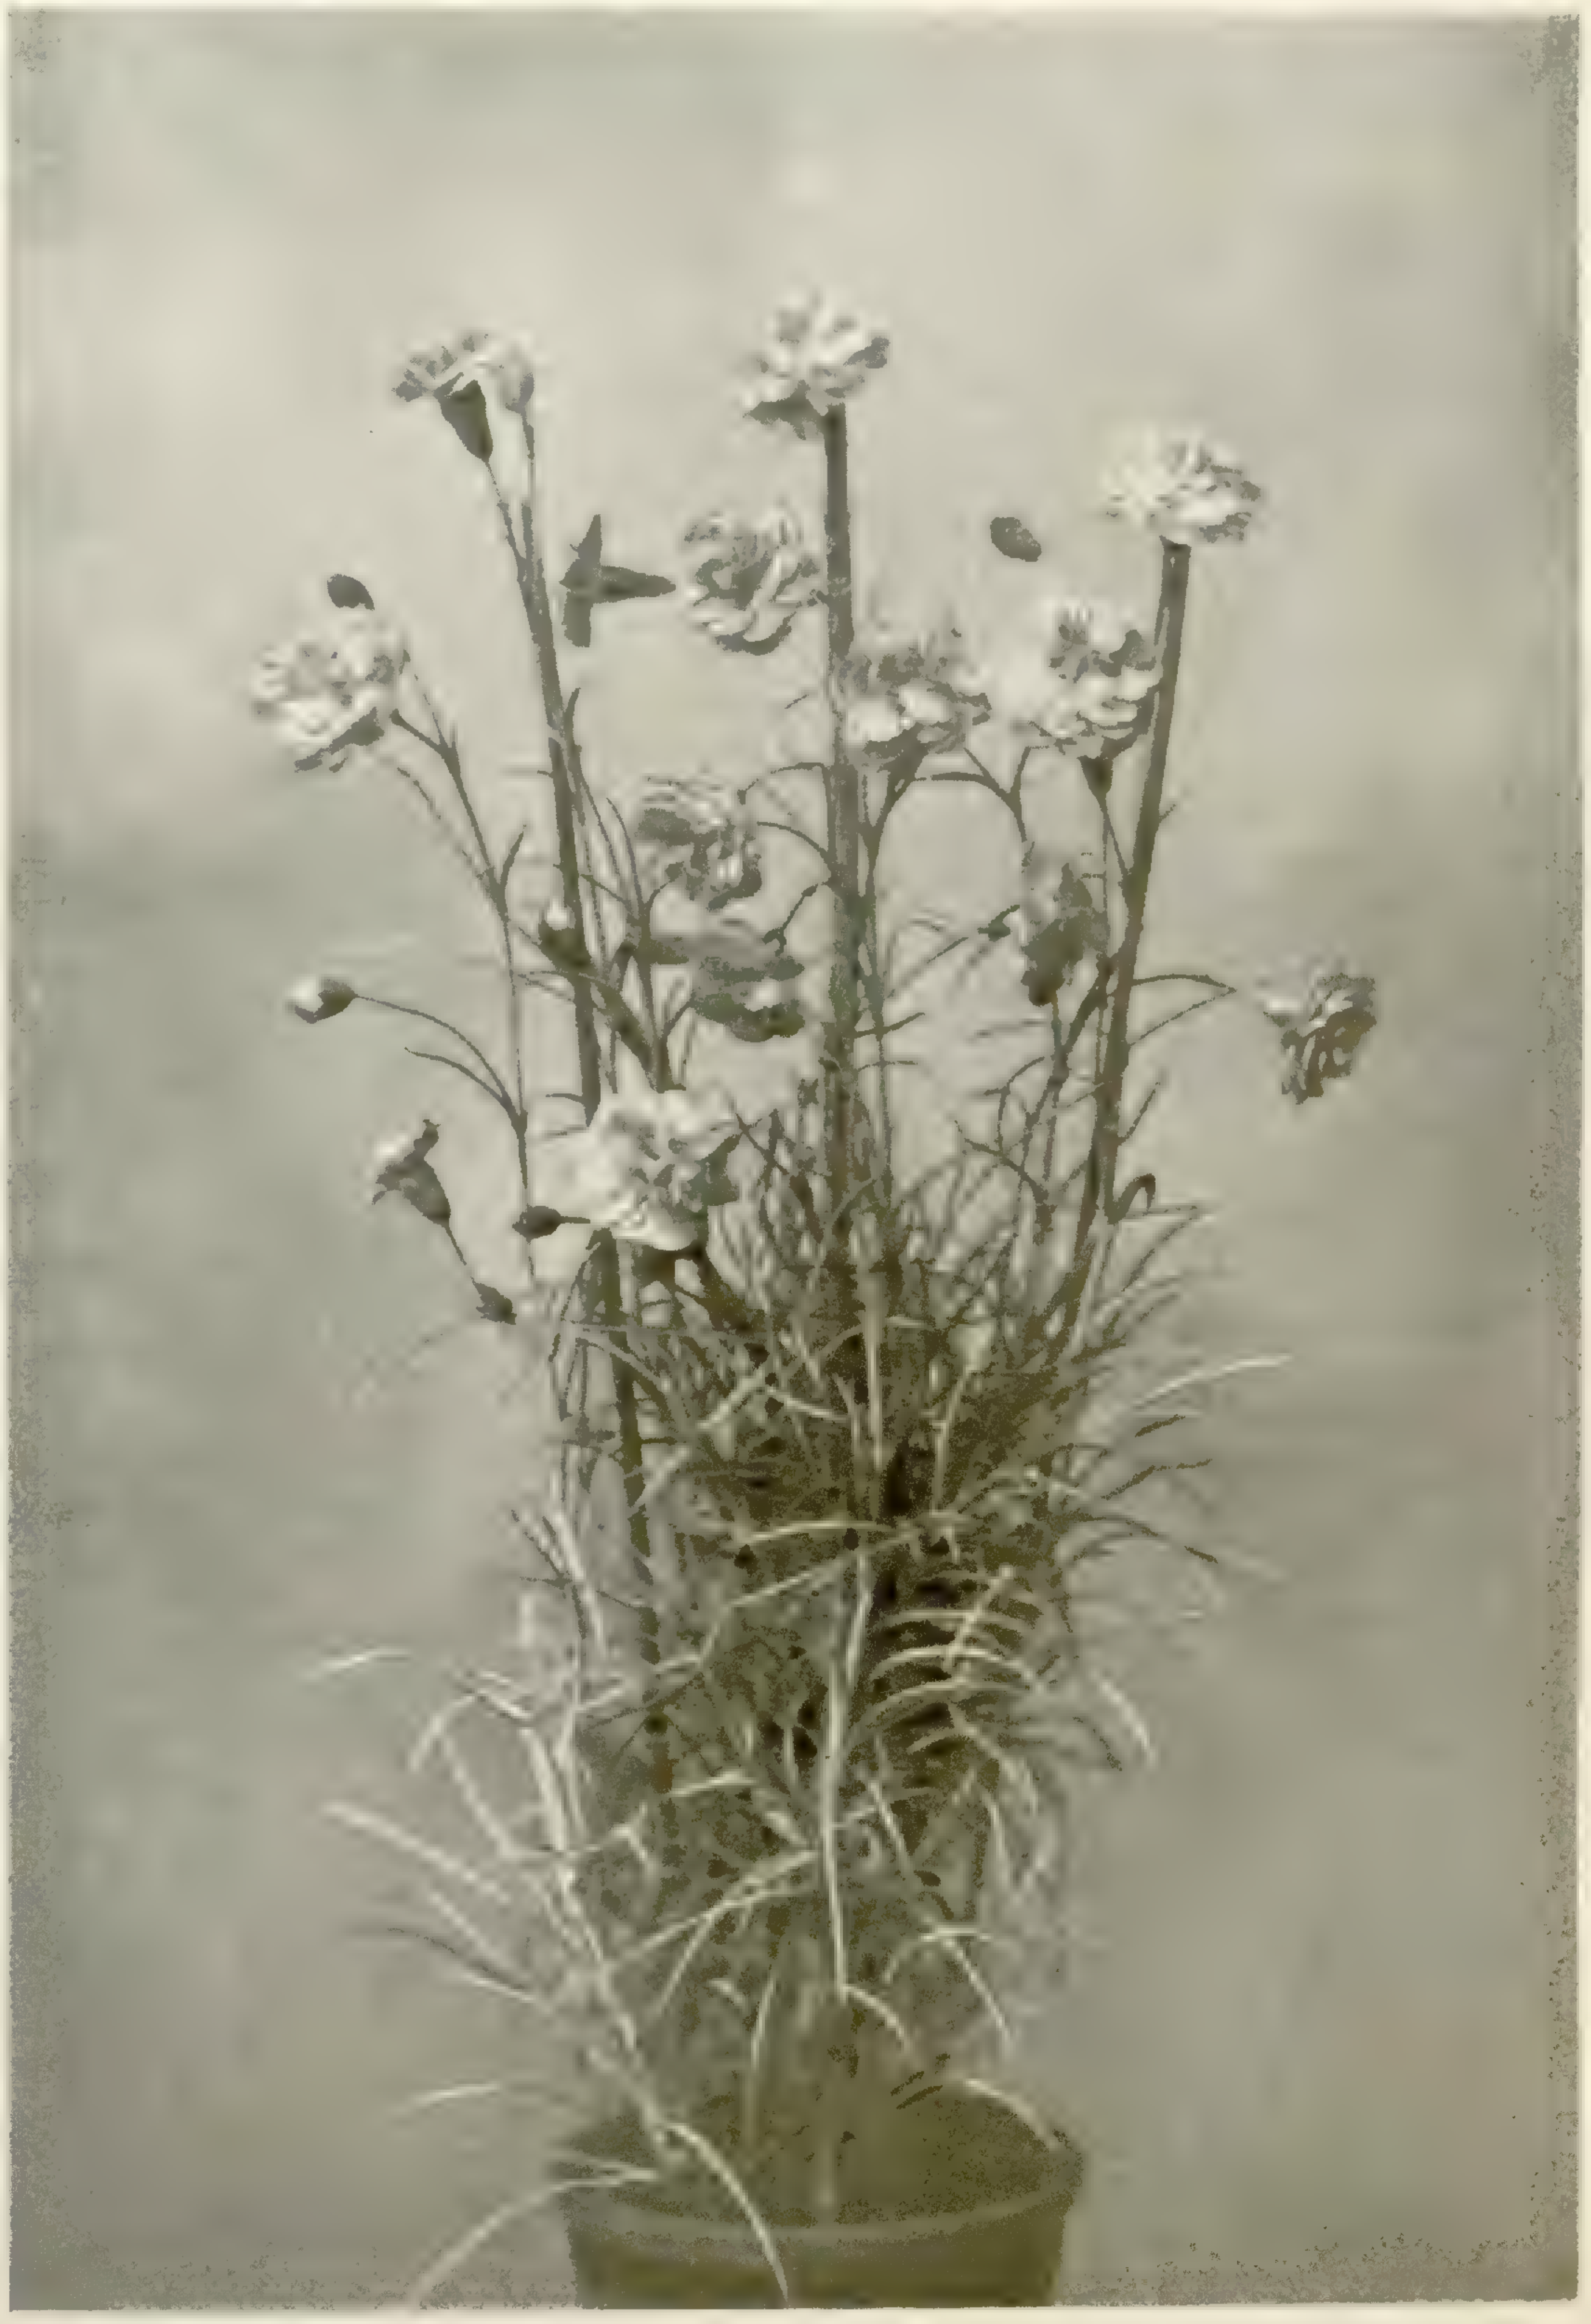
A friend at the Col de la Forclaz wrote: "Perfectly grand weather up here, and not a bit broken yet! Very cold at nights, but magnificent all day. I found eight or nine Gentiana verna to-day on a sunny slope; also polygala in quantity; also Campanula barbata and Geum montanum, and one beautifully fresh tuft of Gentiana germanica. Not bad for October 21!"

The lower slopes of Pilatus were, on October 22, bright with purple milkwort and centaurea, and large mauve scabious, and golden in places with yellow hawkweeds. But a damp chilliness was in the air, which was not only depressing for mortals, but had the effect of depriving many of the beeches of their leaves, which a week before were a blaze of gold and brown.

H. S. Thompson.

NEW PERPETUAL-FLOWERING PINK.

Pinks are so highly appreciated for their elegance, attractive colouring, and fragrance, by the flower-loving community, that the new perpetual variety Progress should have a warm welcome, and attain to a high degree of popularity. This new addition to the list of pinks was raised by Mr. C. H. Herbert, Hazelwood Road Nurseries, Acock's Green, Birmingham, from a cross effected between two of the finest of the laced pinks, namely Chaundy's Arthur Brown, and Thurstan's Robert Houlgrave, and is remarkable for its vigorous habit and freedom and continuity of flowering. The blooms, as so well shown in the accompanying illustration, are of large size and fine form, and the calyx is remarkable for its freedom from splitting, a point of considerable importance in estimating the merit of a pink, whether intended for border culture or for the production of exhibition blooms. The colour is very beautiful, and has been described as rose-mauve. As indicating the vigour of the variety, it may be mentioned that the plants attain a height of about thirty inches, and produce their flowers on long, stiff stalks. Mr. Herbert informs us that the variety was raised three years ago, and that the original plant is still in the position in which it was first planted. Sixty layers were taken off the first autumn, new growth was made freely in the following spring, and in August forty-nine layers were made, seventy-three new shoots taken off for cuttings, and thirty-two spikes of bloom were cut, which is certainly not a bad record for one plant. Progress has received certificates at Birmingham, Shrewsbury, and Wolverhampton.



NEW PERPETUAL-FLOWERING PINK, PROGRESS.
Raised by Mr. C. H. Herbert, Acocks Green, Birmingham. Colour of flowers, rose-mauve.

WORK FOR THE WEEK.

◆

THE ORCHID HOUSES.

SEED SOWING.—It is desirable to reserve a portion of all orchid seeds that have ripened during the autumn and winter months to be sown early in the new year, or as soon after the turn of the days as possible. For the epiphytal kinds, especially the cattleyas and their allies, I do not see that there is any advantage gained by sowing seed during the closing months of the year. Seeds sown then lay in a semi-dormant state for a considerable period, and when they actually start into growth the growth produced is so weakly that the seedlings are subject to damp off. Whereas, plants raised from seeds sown at the present time have the advantage of daily increasing light, and of shading not being required for some weeks to come. Thus there are increased facilities for the rapid germination of the seed, and for the growth of the seedlings during their earlier stages. In the case of the terrestrial kinds it does make a great difference as to what time of the year their seeds are sown. Seeds of cypripediums should always be sown immediately the seed pod is ripened. In sowing seeds of this section several seed beds should be provided on which to sow the seeds, it being a mistake to sow them all on one bed. It will frequently occur that you may sow seeds on, say, half a dozen pots, and in the case of only one may the conditions be favourable to the successful germination of seeds. I have taken seeds from a bed where they have failed to germinate and placed them on a bed where seeds from the same seed pods have been germinating, and found they have produced satisfactory results. Seeds of calanthes also should be sown on different pots, as the conditions are evidently not favourable in every pot for their germination.

The various methods of sowing seeds of epiphytal kinds is now so generally well understood that it is hardly necessary to refer to them There are many who still adhere to the old method of sowing the seeds on selected pots of plants of the kinds to which the particular seeds belong. This appears the only way in which odontoglossum seeds will germinate; I certainly have not discovered a more satisfactory method, but for cattleyas and their allies, dendrobiums, epidendrums, sophronitis, etc., I consider the method too slow. Certainly two or more years can be saved between sowing and flowering by sowing on artificially-made beds. Especially is this the case where every assistance is given to the seeds and encouragement to the plants. I do not think there is any more simple or better method than to take a piece of canvas four or five inches square, lay it in the palm of the left hand, put a handful of chopped sphagnum moss in the centre, roll this firmly into a ball, and place in the centre of a well-drained four-inch pot. Keep the edges of the canvas down by packing it round with chopped moss. Water with rain water, and sow the seeds on the canvas forming the mound in the centre. The pots should be stood in a warm, moist position, and if a propagating case is available take advantage of it. If treated as seeds of ordinary plants there will be little difficulty in securing germination.—H. J. Chapman, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

CONSERVATORY. — As chrysanthemums are now practically over, we are not quite so well supplied with good-sized bright plants for conservatory decoration; but where good batches of arum lilies and poinsettias are grown these will help to carry us on till some of the larger forced plants are in bloom; but for dwarfer plants we are better off, as many of the earlier bulbs are now coming into bloom. They should not be left in the greenhouses till fully in bloom, but as the flowers begin to open they should be gradually inured to the drier air of the conservatory. By this course of procedure they will last some few days longer, a point deserving of consideration.

CHRYSANTHEMUMS.—Those who wish to have good blooms from early in January till the middle of February should at once commence the work of propagation. The stock plants will, in most cases, have had a good rest, and consequently good firm cuttings will be easily procured. These, if not in a frame or house with a very little artificial heat, will most likely overtake plants raised from cuttings that were rooted in November and December. In taking the cuttings they should be obtained as far from the base of the parent as possible, and if there is a danger of rust spores being on them they should be dipped before insertion in a solution of sulphide of potassium, half-an-ounce to the gallon of water. If they are sprayed three or four times while in the small stage, rust will not greatly trouble them afterwards, at least, this is my experience. The cuttings should, if possible, be inserted singly in thumb pots, but if more convenient, they may be put three or four round the sides of a larger three-inch pot. Use a light compost, say, one part each of loam, leaf-soil, and sand, and plunge the pots to the rim in a bed of cocoa-nut fibre refuse in a slightly heated pit. Give sufficient water, and shut the frame up close, and keep them slightly damp by syringing on all bright days. Admit a little air during the night, which will lessen the possibilities of losing the cuttings by damping off, and it will be found that they will commence rooting in three or four weeks, after which they will require air daily.

PROPAGATION.—No time should now be lost in commencing the propagation of various classes of plants that have to be renewed annually, and if not already inserted, a good batch of winter-blooming carnations should be put in at once. These like a nice mild bottom heat, and if short, stout growths are taken off with a heel, they will not be long in rooting, but overhead moisture must not be liberal, or they will probably break into growth before rooting nicely, and this means a weakly growth. Coleus in small pots are always useful for edging groups in the conservatory, and as they are very easily and quickly grown a batch of cuttings may be put in from time to time. I usually put in a pot of cuttings of each variety in the autumn, and these take up little room, and give one, two, or three crops of cuttings during the spring. Cuttings of Abutilon Swatzi may now be rooted, as also may be cuttings of Begonias metallica and Haageana, both of which are excellent for a dark corner of the conservatory, where most other plants would only live a week or two.

SEED SOWING.—Seeds of the following may now be sown: Begonias, gloxinias, streptocarpus, medeolas, Asparagus plumosa, and Schizanthus pinnatus. In the case of the schizanthus I prefer to sow a few seeds in three-inch pots, and thin the seedlings to four or five in each, and shift into 32's or 24's when sufficiently advanced, according to the sized plant required.

GREENHOUSE PLANTS, such as Arum lilies, carnations, cinerarias, cyclamen, primulas, and eupatoriums will now be growing rather more freely with the lengthening days, and in most cases they will require rather liberal supplies of water, also a light top-dressing once a week of some approved artificial manure may be given with advantage, alternated with weak liquid manure, made from horse, cow, or sheep droppings; but give it little and often, rather than in heavy doses, as the soft roots of most of the above-mentioned plants will not stand too heavy manuring. — Thomas Stevenson, Woburn Place Gardens.

THE FLOWER GARDEN.

SUMMER BEDDING PLANTS.—Having decided on the arrangement of the various kinds of plants for the beautifying of the beds and borders during the summer, stock should be taken of the various kinds of plants required, and preparation should be made accordingly. It is well to bear in mind that the better the plants are prepared and established before putting them out the more satisfactory will be the results. Everything should be done that is possible to create an effect immediately the bedding out is completed, and this is accomplished by having the plants of many of the leading kinds well established in single pots. Fortunately, summer bedding has undergone a marvellous change during the past few years; and in the place of pelargoniums, calceolarias, ageratum, lobelia, and similar subjects, each good in its way, one must, to be up to date, be prepared with quite a different class of plants. Without doubt much more pleasing and natural effects are produced by the materials now so freely used. Among these are the new and improved forms of lantanas, abutilons, fuchsias, the fine forms of tuberous and fibrous-rooted begonias, swainsonia, a delightful plant, heliotropes, Plumbago capensis, the old Calceolaria amplexicaulis, C. Burbidgei, the new hybrid forms of ivy-leaved pelargoniums, new bedding verbenas, including Warley Scarlet and Miss Willmott, cannas in variety, salvias, improved forms of Lobelia cardinalis, and many others. All these, when well grown and suitably arranged, form a pleasing and artistic combination.

POTTING.—No time should now be lost in potting off singly the various kinds of pelargoniums, fuchsias, calceolarias, salvias, swainsonias, lantanas, and such-like into three-inch pots. These should be grown on in a temperature of about 50 degrees, and by the end of March, wherever possible, they should receive another shift into five or six inch pots. It is far better to grow half the quantity of plants, and treat them well, than to have double the quantity badly grown.

OLD STOCK PLANTS, which will consist of fuchsias, plumbagos, heliotropes, lantanas, etc., which were potted up, and stored thickly in some frost-proof place, should now be overhauled, pruned back, and started gently into growth, and converted into either bush, pyramidal, or standard specimens. After commencing to grow vigorously they should be shifted into other pots. An early vinery or orchard house will be an ideal place in which to start them.

PROPAGATION.—Much will now have to be done for providing a suitable number of low-growing subjects for carpeting and edging beds filled with tall-growing plants, and these, in nearly all cases make much better material when cuttings are taken from the stock plants and rooted in the spring, they will nearly all root most freely in a propagating pit when the young growth is inserted. Such plants will include verbenas of all kinds, young plants, especially of these, are much to be preferred to old ones. Mesembryanthemum, iresine, coleus, Tropaeolum The Queen (a variegated form, with beautiful dark flowers, a charming plant, which should be much more largely grown), alternantheras, lobelias of the dwarf-growing type, and Lobelia cardinalis in variety. I find the last-named best wintered in a cold frame, and not parted too early, because of it having a habit of dying off when disturbed very early in the year.—E. Beckett, Aldenham House Gardens.

HARDY FRUITS.

FIG TREES in the more southern counties may generally be expected to pass through our ordinary winters without receiving any material damage; but in the Midlands and northern counties some protection is necessary to prevent injury to the young fruiting wood. In the majority of cases in this country, fig trees are usually planted against walls, and therefore can the more easily be protected. Release the branches and at the same time cut clean away any old wood that has become useless; loop the branches together in convenient bundles, and cover each with some light strawy litter or bracken, binding it well round with string to prevent its being blown off by the wind, afterwards making the bundles perfectly secure by fastening them to the wall with a piece of stout cord.

CORDONS, whether growing horizontally, obliquely, or upright, will require treatment according to their condition. If the trees have room for extension, shorten the leaders in proportion to the growth, and for the proper development of the fruit spurs, always prune close to a healthy bud which promises to furnish a growth suitable for training in the direction required. Remove old ties, and, if necessary, scrub the main branches with soapy water before retying.

MORELLO CHERRIES produce the greater portion of their fruits on young wood of the preceding season's growth, therefore sufficient of the older wood should be removed each season to allow of the new growths being laid in. Superfluous young shoots should be cut back to within an inch of their base to form fruiting spurs; remove the trees from the walls, loop the branches together in convenient bundles, and spray with an insecticide to destroy any black fly which may be secreted in the axils of the buds, as these, if not destroyed during the winter, prove very troublesome when the trees are in leaf. Re-fasten the trees to the walls, allowing on an average about four inches between the growths.

THE SLUG WORM (Selandria atra) was very prevalent in these gardens some eight or nine years ago, and destroyed a large amount of foliage on the pear and cherry. During the following winter we gave the soil, as far as the branches extended, a good soaking of diluted gas-water, i.e., one gallon of gas-water to six of clear water; this proved most efficacious in destroying the cocoons, as no signs of this pest have been noted until this last summer, when a few isolated larvæ were seen on the pear. We are now repeating the experiment which has hitherto proved so satisfactory. The gas-water contains a certain proportion of ammonia in its composition, which is beneficial to most hardy fruits, but the liquid must always be diluted as advised above.—Geo. Woodgate, Rolleston Hall Gardens.

A Laburnum Avenue.—Now that pergolas and arches over which flowering plants are trained are so popular, a pleasant change could easily be introduced by planting an avenue wholly, or mixed among other subjects, of standard-grown trees of Laburnum Waterer's Hybrid, which is probably the best for flowering in May and June. If a succession is required, then plant the Scotch variety, L. alpinum, which is an elegant-growing form. Trained over an archway or pergola, the golden racemes produce a very fine effect.—E.

GRAND YORKSHIRE GALA
AND
FLORAL FETE AT YORK.
JUNE 16th, 17th, and 18th, 1909.
PRIZES £800.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

Royal Horticultural Society.

The first meeting of the year was well attended, but the exhibition was not a large one. Orchids were fairly plentiful, and ferns and carnations, with a big group of stove plants, almost made up the display.

FLORAL COMMITTEE.

Right opposite the entrance, filling a central position on the far side of the hall, Messrs. Jas. Veitch and Sons, Chelsea, put up one of their fine exhibits of stove plants, orchids, etc. Every plant represented excellent culture, and the crotons were very fine indeed. Dieffenbachia Fournieri, Phyllotænium Lindeni, Heliconia illustris rubricaulis, Anthurium crystallinum, Coccoloba pubescens, Alpinia Sanderiana, and Phœnix Roebelini were all grandly represented, and there were excellent examples of Nepenthes Morganiæ, N. Chelsoni excellens, N. Hookeriana, and N. Dicksoniana. The flowering subjects included a central group of odontoglossums and lycastes, flanked by small groups of hybrid cypripediums, camellias, Javanico-jasminiflorum rhododendron hybrids, Crowea latifolia, Begonia Agatha, the bright blue Coleus thyrsoideus, Primula Kewensis, Gomphia olivæformis, and some amaryllis. The whole group was arranged in a very pleasing and effective manner, and was the great feature of the exhibition. The Messrs. Veitch had also a group of perpetual-flowering carnations, showing these as growing plants in pots, and staging the leading varieties.

A pretty group of perpetual carnations was tastefully arranged by Mr. H. Burnett, Guernsey, who had very bright, clean, but not over-large flowers of Mrs. H. Burnett, Marmion, Mikado, Enchantress, Britannia, Afterglow, and Winona, and some yellow seedlings. Very beautiful and interesting were the finely-grown bertolonias shown by Mr. L. R. Russell, Richmond. Each plant was in a pan and covered with a bell-glass. The exquisite colouring and venation of these plants is beyond description, the blue and green and silver being most subtly intermixed. The varieties represented were B. Mdme. Van Houtte, B. Souvenir de Gand, B. Comte. de Kerchove, B. Mdme. A. Bleu—a fine silvery-variegated form; B. Cerise cristata, and B. Mdme. Ed. Pynaert.

Messrs. Barr and Sons, Covent Garden, exhibited a number of pretty snowdrops, and a little collection of early crocuses; with these were red and yellow-barked willows, Iris stylosa, hellebores, Cyclamen coum roseum, Gaultheria procumbens, and some saxifragas.

Mr. Herbert Chapman, Guldeford Lodge, Rye, submitted the charming Freesia Chapmani, and a number of seedlings, as well as the pinkish hybrids raised by Ragioneri. Mr. N. Molyneux, Rookebury Park, Fareham, showed a pretty late white chrysanthemum, named Maud Allan (A.M.), a fine decorative variety. A pretty little wild cyclamen from Palestine was shown by Mr. A. W. Sutton, Bucklebury Place, near Reading. The new Begonia Patrie (A.M.), a cross between B. socotrana and B. Pearcei, was shown by Messrs. V. Lemoine and Son, Nancy, France; this has small, pretty carmine-pink flowers, and is a free bloomer.

A particularly fine group was the one so admirably arranged by Mr. W. H. Page, Tangley Nurseries, Hampton. It consisted of big stands of Lilium speciosum and L. longiflorum, with large vases of Mrs. T. W. Lawson, Marmion, White Perfection, Enchantress, Governor Roosevelt, Winsor, and Mikado carnations, in front of them, and with a small group of Golden Spur daffodils in the middle. Messrs. Hugh Low and Co., Bush Hill Park, Enfield, showed good batches of Dracæna Victoria, D. De Grooti, and D. Prince Albert, as well as a selection of winter-flowering carnations and some good cyclamen. The contribution from Messrs. W. Cutbush and Son, Highgate, consisted of hardy flowers, such as Hamamelis arborea, Daphne Mezereon, Cyclamen coum, crocuses, Iris histrioides, etc.

A large and very interesting exhibit of ferns was arranged by Messrs. H. B. May and Sons, Edmonton, and the feature of the exhibit was the display of small creeping ferns grown on short tree fern stems, and among these we made special note of Polypodium repens, P. piloselloides, Asplenium obtusalobum, Polypodium vaccinifolium, Drymoglossum spathulatum, and Niphobolus rupestris. Other polypodiums were largely represented, and the whole exhibit attracted a great deal of attention.

ORCHID COMMITTEE.

A charming group of orchids, in which beautiful odontoglossums and graceful lælias figured largely, was set up by Messrs. Charlesworth and Co., Hayward's Heath. The white varieties of Lælia anceps were very beautiful and filled the centre of the display. On one side were numerous examples of Cattleya Octave Doin, and a few of the yellow L.-c. Andromeda and C. Percivaliana alba (F.C.C.). On the other side were some delightful plants of Odontoglossum ardentissimum, in variety, O. Armaimvillierense Xanthotes, O. Lambeauianum, O. crispo-Harryanum, and O. Bohnhofiæ. A few other good things were Sophro-cattleya Doris, Cypripedium Beckmanni, C. Baron Schroder, and Saccolabium bellinum. Mons. Mertens. Ghent, contributed a few beautiful cross-bred odontoglossums of remarkable colouring, but none of them were labelled.

Mr. J. Collier, gardener to Sir Jeremiah Colman, Bart., V.M.H., Gatton Park, Reigate, showed several forms of Lælia anceps, Phaio-calanthe Colmani, Cymbidium grandiflorum, C. Lady Colman, Spathoglottis Colmani, and the curious Warscewiczella valata. From Messrs. Hugh Low and Co., Bush Hill Park, Enfield, came some good cypripediums and odontoglossums, the former including C. Helen II. Cattleya Leda and C. Maggie Raphael were shown by Mr. R. G. Thwaites, Chessington, Streatham; a fine specimen of Masdevallia ignea, from Mr. Ballantine, gardener to Baron Schroder, The Dell, Egham, gained a Cultural Commendation. Mr. W. H. White, orchid grower to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, showed a fine brown odontoglossum named O. Swietenia-color, surely a queer name, and given, we understand, because the chief floral colour resembles mahogany (Swietenia).

Messrs. J. and A. McBean, Cooksbridge, submitted the fine Cypripedium Memoria Jerninghamiæ, some good odontoglossums, and Lælia anceps. Mr. Walter Cobb, and Mr. H. T. Pitt both sent cypripediums. Mr. A. W. Jensen, Lindfield, Hayward's Heath, showed a few good white ground odontoglossums. Messrs. Armstrong and Brown, Tunbridge Wells, showed Cypripedium Venus, Oakwood var., C. Helen II. Armstrongæ, C. Maudiæ, etc. Mr. Francis Wellesley, Westfield, Woking, sent the pretty little Sophrocattleya Mrs. Francis Wellesley, a rosy flower obtained by crossing C. labiata with Sophronitis grandiflora. Mr. Alexander, orchid grower to Lieut.-Colonel Holford, Westonbirt, Gloucester, staged a couple of good plants of the pure white and graceful Vanda Watsoni (A.M.), Cattleya Maggie Raphael Westonbirt var. (A.M.), with beautifully-coloured lip; Brasso-cattleya Mrs. J. Leeman var. Rajah, and the handsome Cypripedium Bellerophon. Mr. H. J. Chapman, gardener to N. C. Cookson, Esq., Oakwood, Wylam-on-Tyne, brought up Odontoglossum ardentissimum Norman Cookson (A.M.). Mr. Bromilow, Rann Lea, Rainhill, sent Cypripedium Bromilowæ, another albino of Charlesworthi style; and C. Œson giganteum (F.C.C.).

Miss M. Walters-Anson, Dovedale, Streatham, contributed a small collection of orchid paintings, all well executed.

FRUIT AND VEGETABLE COMMITTEE.

From the University College, Reading, Mr. Chas. Foster brought up excellent samples of Sutton's Eclipse and Sunbeam tomatoes, sown July, 1908; French Frame cabbage lettuce, sown September 16, 1908; and Early Nantes carrots, from the open ground, without protection. A large number of seedling apples were contributed, and Mr. Allan, Gunton Park Gardens, exhibited a dozen good fruits of The Blickling pear.

In the competitive class for a pair of bunches of late grapes, Mr. W. Lintott, gardener to Sir Walpole Greenwell, Bart., Marden Park, Woldingham, secured first prize with good examples of Lady Downes.

CERTIFICATES AND AWARDS.

First-Class Certificate.—Cattleya Percivaliana alba, from Messrs. Charlesworth and Co., Hayward's Heath; Cypripedium Œson giganteum, from Mr. Bromilow, Rann Lea, Rainhill, Lancs.

Award of Merit.—Cattleya Maggie Raphael Westonbirt var., and Vanda Watsoni, from Mr. Alexander, orchid grower to Lieut.-Colonel Holford, Westonbirt, Gloucester; Odontoglossum ardentissimum Norman Cookson, from Mr. H. J. Chapman, gardener to N. C. Cookson, Esq., Oakwood, Wylam-on-Tyne; Begonia Patrie, from Messrs. Victor Lemoine and Co., Nancy, France; Chrysanthemum Maud Allan, from Mr. N. Molyneux, Rookesbury Park, Fareham.

MEDALS.

Gold.—Messrs. James Veitch and Sons, Chelsea.

Silver-Gilt Flora.—Mr. W. H. Page, Tangley Nurseries, Hampton; Messrs. H. B. May and Sons, Edmonton; Messrs. Charlesworth and Co., Hayward's Heath.

Silver Flora.—Mr. L. R. Russell, Richmond.

Silver Banksian.—Mr. H. Burnett, Guernsey; Messrs. W. Cutbush and Son, Highgate; Messrs. Hugh Low and Co., Enfield, one for dracænas and one for orchids; Mr. J. Collier, gardener to Sir Jeremiah Colman, Bart., V.M.H., Gatton Park, Reigate.

Cardiff Gardeners' Association.

The fortnightly meeting of the above association was held at St. John's Schools, on the 5th inst., Mr. H. R. Farmer, F.R.H.S., occupying the chair. A lecture and demonstration on "The Manipulation of Florists' Flowers" was given by Mr. Sydney Case, of Cardiff. The lecturer described the present method of wiring flowers, which is a decided improvement on the method in vogue in years gone by. The most delicate kinds of flowers were shown to the members, who were very much interested in the masterly manipulation and grand display which Mr. Case had provided.

On the motion of Mr. Mague, seconded by Mr. G. Drake, a hearty vote of thanks was accorded Mr. Case for his interesting, instructive, and much-appreciated lecture, and this was suitably acknowledged.

Chester Paxton Society.

The members forming the Executive and Districts Committees of this society accepted an invitation to dinner from their respected chairman, Mr. A. W. Armstrong, at the Blossoms Hotel on Saturday last. About thirty sat down to an excellent repast, which was presided over by Mr. Armstrong, and he was ably supported by Mr. J. D. Siddall, Mr. N. F. Barnes, Mr. J. Simon, and Mr. G. P. Miln (hon. secretary). After the dinner an excellent programme of music was well rendered by Messrs. G. H. Plant, W. C. Armstrong, W. Fergusson, S. Dring, W. H. Harker, and A. E. Ward, the latter also acting as accompanist. The music was interspersed with toasts and speeches, including "The King," "The Paxton Society," "The Chairman," "The Visitors," and "The Artistes." The singing of "Auld Lang Syne" and "God save the King" by the company brought a very pleasant evening to a close.

Beckenham Horticultural Society.

Notwithstanding a local snowstorm, there was a large gathering of the members of this society at the Church House, Beckenham, on Friday, January 8, to hear Mr. Chas. H. Curtis lecture on "Sweet Peas and Their Culture." Mr. A. J. Baker, of the Kent County Council, presided. Mr. Thos. Crosswell, gardener to Mrs. Bullivant, Homewood, Beckenham, showed two very fine specimens of Cypripedium insigne, one of them, in a six-inch pot, carrying 43 flowers.

Mr. Curtis gave the history of the sweet pea, an account of its evolution, methods of cultivation, modern varieties, and the work of the National Sweet Pea Society. He was heartily thanked for his lecture.

APPLE SALES.

"E. M.," page 37, is quite welcome to any opinion he may have respecting my experience of apple sales, but I rather fancy he has a few more wrinkles to learn himself, or he would succeed in selling his apples better. Everybody knows that the imports of foreign apples affects the prices of home-grown produce; but, in spite of "E. M.'s" arguments, I still contend that the selling of late-keeping apples of the Bramley's Seedling type in September and October has a considerable effect in over-stocking the markets at the above season, and keeping down prices. As a matter of fact, there was a perfect slump of apples in my own district last autumn, and it was brought about largely by the gales of wind which blew off large quantities of fruit that were rushed into the markets and sold for what they would fetch. Naturally, the overwhelming abundance of this class of produce affected the sale of the best. As your correspondent seems to know all about apple sales, it may be no news to him to hear that in December Bramley's Seedlings and Newton Wonders were sold in wholesale fruit markets in the West of England for 16s. and 18s. per cwt. Would the same apples have fetched as much money if they had been sold in September, October, or even November? Hardly, even though in all probability there are more foreign apples about now than there were then. Though "E. M." has such a poor opinion of my knowledge and experience, I will not question his, but, in comparing his figures with the above, it is evident that markets are either better in some districts than others, or else "E. M." was too anxious to sell.

H.

The Moonlight Broom. — There are few more lovely things than good plants of the common broom, Cytisus scoparius, and those who have frequent opportunities of seeing it in plenty by the wayside and the wilds need ask for nothing more beautiful. In our gardens, too, we have C. scoparius Andreanus and the several lovely varieties which have sprung from it of recent years. Very beautiful are these, but the brooms are all so beautiful that many of us may find room for the Moonlight one, C. scoparius pallidus, which has flowers of a beautiful creamy white, not, after all, unlike the pallid light of Luna herself. In the garden or the wild garden it is a beautiful thing, with its blooms the size of a good variety of the common broom, but distinct in its tone of colour. Like the others of its class, the Moonlight Broom should be well cut back after flowering. Hard cutting back not only conduces to greater shapeliness, but also to much greater freedom of flower. A dry bank suits this broom well.—S. Arnott.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

RHUBARB.—M. A., Devon: The old stools will give useful supplies if lifted and placed in a mushroom house or other structure, in which a temperature sufficient to stimulate growth is maintained. Medium-sized stools with three or four well-developed crowns are preferable, as all the "sticks" will then be of good size and uniform in development. We would suggest that you plant a fresh bed each year for maintaining a succession of young crowns for yielding early supplies. Old stools should be divided into portions having two or three crowns each, and remain in the beds two years. Deep digging and liberal manuring are essential to success in the preparation of roots for the production of early supplies.

BEAUTIFUL-LEAVED TREES.—R. B., Hants: As you have not devoted any considerable share of your attention to the study of tree life, you cannot have an adequate idea of the number and beauty of the trees with leafage and colours other than green, because of their paucity in gardens, even when the area comprises many acres. Therefore we would strongly advise you to visit neighbouring nurseries and botanic gardens within a convenient distance during the summer and early autumn for the purpose of becoming acquainted with them. We have frequently urged the more extended use of trees with richly-coloured leafage, but we have been careful to avoid being understood as suggesting that they should predominate. So far from this being the case we would direct special attention to the fact that in the garden, as in the field and woodland, Nature's scheme of colouring should be adopted. Or, in other words, the prevailing colour should be green, with masses of silver and gold and crimson to light it up, and bring out by way of contrast the various shades of green afforded by the numerous trees and shrubs. Whilst it is not possible to enter fully into the details of the arrangement of trees with brightly coloured foliage, it may be useful to point out that the practice so common of distributing each of the kinds selected over the garden should be avoided. The best method of dealing with them is to arrange, as far as it can be done, each form in a group by itself, the number of trees in each to be determined by the space available and the area of the garden. In extensive pleasure grounds the groups may be repeated, but as it is most desirable each part should present some new feature or effect, the greatest possible care must be taken to avoid unnecessary repetitions. In some cases single specimens will be admissible, and indeed desirable, more particularly in the case of the golden conifers, but care must be taken to plant them where they will have space for their full development, and amid suitable surroundings.

LEGAL QUESTION. — F. H. M., Yorkshire: We are anxious to assist our readers to the fullest possible extent; but your question is a purely legal one, and has no reference to the garden, except so far as its tenure is concerned as a part of the dwelling-house. Moreover, the question could only be answered after a careful examination of the lease, and the correspondence relating to repairs. We suggest that you consult a solicitor of standing.

DESTRUCTION OF VERMIN. — Most gardens are pestered with Rats and Mice. Every effort should be made at this time of the year to exterminate them before seeds are sown. Danysz Virus is first rate stuff for killing these vermin. Single tube, 2s.; three tubes, 5s. Post free from DANYSZ VIRUS LTD., 52, Leadenhall Street, Garden Dept., London, E.C.—[Advt.]

NITRO-BACTERINE. — Amateur, Essex: The whole matter is in an elementary stage, and too much importance should not be attached to reports, whether they be favourable or otherwise. Further experiments are necessary, but to have much value they should be conducted in a systematic manner under diverse conditions in different parts of the country. The application of bacteria cultures will, it may be assumed, prove useful to leguminous plants on soils that are deficient in beneficent micro-organisms, but it is not probable that they will have the effect of greatly increasing the crops of such plants in highly-cultivated ground that is rich in humus. You might conduct a few trials with leguminous crops; they would be interesting, and the cost would not be great.

VALOTTA PURPUREA.—Mr. C. Thrower, gardener to Mrs. W. Matthews, Chesham Park, Anerley, writes with reference to this handsome bulbous plant: "I have read with much interest 'T. B.'s' notes on Valotta purpurea, and I fully agree with him that satisfactory results cannot be obtained by indifferent treatment. I also agree with him that the bulbs require repotting every second or third year. Those under my charge are repotted every second year, but not in August, as your correspondent advises. In that month my plants are producing their scapes, and the flowers are invariably at their best the first week in September. I have exhibited the specimens on several occasions, and they have always been shown in that week. I enclose a photograph of three specimens grown in a 12-inch pot, and bearing thirty-one, thirty, and twenty-nine spikes, each spike bearing five or six flowers. After the flowers have lost their freshness and beauty water is given sparingly to induce the bulbs to pass into a state of rest. They are not dried completely off, as I consider that undesirable. The flowers are removed as they lose their beauty, and thus seeding is prevented, which would impose a tax on the bulbs. The spike is allowed to die down naturally, and not cut away while in a green state, much sap being lost when so cut, to the injury of the bulb. After the spikes have died down naturally, the decayed leaves are removed. In repotting, which is done in January, the bulbs are shaken out, and all the young bulbs are removed. They are put in 10-inch pots, nine in each, and a compost consisting of good loam, spent mushroom bed, and some mortar, is used. The pots are, of course, efficiently drained. [The photograph sent by Mr. Thrower fully justifies the course of procedure he has adopted, and represents specimens that are quite exceptional in their development. We regret the photograph is not suitable for reproduction.]

BOUGAINVILLEA GLABRA.—N.: This beautiful climber is equally at home in the plant stove and warm conservatory, and you might plant it with advantage in your spacious structure. It should be planted in a well-drained border.

LILACS FOR FORCING.—R. B., Dorset: It is a mistake to suppose that lilacs suitable for forcing cannot be as successfully grown in this country as in France, and many proofs of this could be given were it necessary. But to achieve success in the production of plants for flowering under glass a well-devised course of procedure must be followed. The first step is to select varieties such as Charles X., Marie Legray, Madame Lemoine, and Dr. Lindley, that are adapted to the purpose, and the next is to grow them in such manner as will ensure their having an abundance of fibrous roots and stout, short-jointed wood well furnished with flower buds. Strong healthy suckers should be selected, and planted in an open position, the distance to be twelve inches apart in rows with two feet spaces between them. The planting should be done some time between the end of October and the end of February, but the sooner the better after the beginning of November. Previous to new growth commencing, cut them down to within about nine inches of the surface of the ground. In the following November lift and replant eighteen inches apart in rows, with two and a-half feet spaces be-

Burpee's

The Leading American Seed Catalog for 1909!

The "SILENT SALESMAN" of the World's Largest Mail-Order Seed Trade is a **New BOOK of 174 pages.** It describes Rare Novelties which cannot be had elsewhere, and tells the *plain truth* about the Best Seeds that can be grown—as proved at our famous FORDHOOK FARMS—the largest and most complete Trial Grounds in America. Handsomely bound in covers lithographed in nine colours, it shows, with the beautiful coloured plates (also in nine colours), Seven Choice Novelties in Vegetables, Three Superb "Spencer" Sweet Peas, and the most beautiful new Giant-flowered Pansies—all accurately painted from nature. With hundreds of illustrations from photographs and carefully-written descriptions, it is A SAFE GUIDE to success in the garden, and should be consulted by everyone who plants either for pleasure or profit. While too costly a book to send unsolicited (except to our regular customers), we are pleased to mail it **FREE to every one** who *has a garden*, and can appreciate QUALITY IN SEEDS. Shall we mail YOU a copy? If so, kindly *name this paper* and **write TO-DAY!**

NOVELTY OF THE SEASON.

"PROGRESS,"
NEW PERPETUAL FLOWERING PINK.

It is quite distinct from any other pink; flowers a lovely rosy-mauve, of perfect form and calyx, borne on long, stiff stems, and with delightful fragrance; a grand border flower; also excellent for pot culture. Price 3s. each, or 5s. per pair.

C. H. HERBERT, The Nurseries, Hazelwood Road, Acock's Green, Birmingham.

tween them. During the winter shorten the shoots to about one-half their length. By the following winter they will have made neat bushes, and may be lifted and potted up for flowering in the following spring, provided, of course, they are well furnished with flower buds. The potting should be done quite early in November, and pots be used just large enough to hold the roots with a moderate quantity of rich compost about them. Those not provided with flower buds or having but few should be replanted, and have a little more space than they were allowed in the bed from which they were lifted. When required for forcing into bloom early in the year, it is advisable to grow the plants in pots during the previous year. They should be potted up in the second autumn,and put in pots of a suitable size with a rich, substantial compost. Throughout the winter and the following summer the pots should be stood on a thick bed of ashes, or a hard surface, and have loose material packed about them. When making their growth an occasional supply of liquid manure of a moderate strength will be of considerable assistance.

ACACIAS. — F. M. W., Middlesex: The number of acacias suitable for gardens in which the space under glass is limited, and the conservatory of moderate dimensions is small, but the following would form a suitable selection for your purpose: A. armata, A. Drummondi, A. grandis, A. longifolia magnifica, and A. pulchella. These are all suitable for pot culture.

PEACH BORDERS.—W. Smith, Beds: It is quite true that peach and nectarine trees growing under glass should enjoy a thorough rest during the late autumn and early winter months; but this rest should not, as you have been advised, be brought about by keeping the border dry. Erroneous ideas on some points of practice would appear, from the advice you have received, to die hard. That relating to the desirability of keeping indoor peach borders dry for the purpose of ensuring a thorough rest to the trees, is certainly very tenacious of life, although every peach or nectarine growing in the open is a proof that a liberal amount of moisture in the soil does not prevent the trees enjoying the complete rest essential to successful results. It is not advisable to keep indoor borders so wet from the beginning of November till the end of January as the outside borders usually are, but the soil should be maintained in a moist state. When borders in which trees under glass are growing are allowed to become dry, and remain so for even a short period, the trees usually shed prematurely a considerable proportion of their buds.

HOLLYHOCKS.—R. Morris, Kent: Hollyhocks raised from seed sown at once, and grown on steadily until the season is sufficiently advanced for them to be bedded out, will produce good spikes of bloom at the end of the summer or early in the autumn. Seed from a good strain, such as may be obtained from any of the seedsmen advertising in these pages, will produce a good percentage of plants bearing double flowers. If a considerable proportion are single or semi-double it will not matter, as both single and semi-double varieties are extremely beautiful. It is important to sow the seed at once, and to shift on the seedlings as may be necessary to prevent them becoming pot-bound before they are transferred to the borders. We need hardly state that the latter should be liberally dressed with manure and deeply dug.

NAMES OF FRUITS.

W.—1, Newton Wonder; 2, Rambour Papaleu.

N. M.—1, Belle Angevine; 2, Winter Orange.

R. Thomson.—1, Catillac; 2, Easter Beurre.

K. S.—1, Hormead Pearmain; 2, King of Tomkins County.

Amateur.—1, Mannington's Pearmain; 2, Bramley's Seedling; 3, Pomme Gris.

S. B.—Probably a local seedling; it is of no merit, and we would suggest grafting the tree with a variety of high quality.

NAMES OF PLANTS.

H. S.—A poor form of Cattleya Percivil-iana.

S. T. H.—The camellias are: 1, Alba plena; 2, conspicua; 3, Donkelaari.

F. — 1, Odontoglossum ardentissimum; 2, Masdevallia ignea; 3, Cypripedium insigne Sanderæ.

B. W.—A good type of Primula obconica, but not of sufficient merit to justify a varietal designation.

B. F.—1, Phyllanthus mimosæfolius; 2, Maranta alba lineata; 3, Pothos celatocaulis; 4, Asparagus declinatus.

M.—We cannot undertake to name florists' flowers, and, owing to the blooms of the carnations having been wrapped in dry cotton, they were so much shrivelled when they reached us as to be quite past recognition.

WARE WIREWORMS!

Of all insect pests that ravage flower and kitchen gardens, the wireworm is the deadliest. The damage it does annually is appalling.

To exterminate the wireworm, the centipede, the leather jacket, the eel-worm and the millipede that ruin your garden, use

KILOGRUB

the surest and most effective pest-destroyer yet produced, and use it **now.**

"Kilogrub" is a chemical powder, which, well worked into the soil, gives out fumes which are fatal.

No insect pest can live on "Kilogrub" treated soil.

Only 2 or 3 ounces are necessary for a square yard.

Remember:—Kilogrub is a proved success—try it to-day.

Prices, cash with order carriage paid:—

V1 FLUID
THE WINTER SPRAY FLUID.

The Priory Gardens, Roehampton, S.W. November 14th, 1908.

Sirs,—I purchased 2 gallons of V1 and sprayed about half the trees under my charge here, doing the other half with another preparation. I have much pleasure in saying that V1 has exceeded my expectations; the trees kept clean all the Summer, with the exception of a slight attack of Green Fly upon the young shoots of some plum trees, which was soon got rid of by an application of V2 Fluid. I have no hesitation in saying that if your two Fluids are as effectual in the future as they have been here this season, no one need have dirty trees or maggoty and misshapen fruits.

Yours respectfully, **D. CAMPBELL.**

V1 FLUID IS EASY TO MIX AND EASY TO APPLY.

1 Gallon of Fluid makes 100 Gallons of Spray Mixture.

OBITUARY.

◆

MR. DAVID CROLL.

There were laid to rest in Barnhill Cemetery, Broughty Ferry, on Monday, 11th inst., the remains of Mr. David Croll, the well-known rose-grower, and who for many years occupied a foremost place in Scottish horticultural circles. To those who knew him intimately, Mr. Croll's death caused no surprise, as he had been in failing health for some considerable time. Born at Duntrune, near Dundee, sixty-eight years ago, where his father carried on the trade of a miller, Mr. Croll as a boy entered the service of his uncle, Mr. P. W. Laird, nurseryman, Broughty Ferry, under whose tuition he acquired a thorough insight and knowledge of the practical and higher branches of the business. Subsequently, to acquire greater experience, he engaged with Messrs. Alexander Cross and Sons, seedsmen, Glasgow, in whose service he remained for a number of years. Returning to his native district about thirty years ago, he started business on his own account, taking into partnership with him his brother William, and for many years the firm of Messrs. D. and W. Croll, Dundee, has occupied a leading place among the horticulturists of the kingdom. Mr. Croll is survived by a widow and two sons and two daughters, the eldest son now succeeding his father in the business.

50 in 12 varieties - - 15/-

HELIANTHUS.

From August to October provide a glorious display of rich golden yellow flowers most useful for cutting.

12 in 6 varieties - - - 6/-
50 in 6 varieties - - - 21/-

To that great army of enthusiasts whose leisure is limited.

EASY culture and extreme hardiness, allied with bloom-producing qualities of the highest degree of excellence in colour, shape and size distinguish this collection of five. Where such a desirable combination exists, gardening becomes a REAL recreation, not an unwelcome extension of the day's work; a minimum expenditure of time and labour is rewarded by a maximum of results.

Choose your own position for any one of the five. PLANT THE WHOLE OF THEM NOW in ordinary garden soil, and, without any heavy demand on your time or knowledge, next summer, and many summers to come, will see a living mosaic of glowing colours in your garden.

Coming from York Nurseries, the headquarters of hardy plant culture in this country, each plant is necessarily a picture of robust health, requiring only air, water, and a moderate amount of sunshine for development.

Send your order along to-day. Packing free for cash; carriage paid on lots of 10/- or over in value.

NOW IS THE TIME TO PLANT (the best time of the whole year) KELWAY'S BEAUTIFUL BLUE DELPHINIUMS. Hardy, and flourishing in every garden, they are the STATELIEST of PERENNIAL PLANTS for borders or beds; these celebrated improvements are invaluable for their introduction of that precious colour—blue—in masses to the garden. KELWAY and SON developed this race, and they should be procured direct from the Royal Horticulturists, Langport.

KELWAY'S IMPROVED DELPHINIUMS are now ready, strong plants, in choice named selections. Collection "B," 15s. per doz. Collection "D," 42s. per doz. Delivery free for remittance with order. KELWAY and SON, The Royal Horticulturists, Langport, Somerset.

FOR PRESENT PLANTING.

PLANTERS of FRUIT TREES should write for our fully descriptive catalogue and supplement, 6d., post free; and gratis to customers.

Well-ripened trees of all kinds, and our large, developed specimens of Vines, Figs, Peaches, and Nectarines, are especially good.

An inspection solicited.

TO-DAY! AND FOR YEARS AND YEARS PAST the XL ALL Specialities are and have been the best on the market. Where is the Gardener who does not pin his faith to one or the other of these celebrated Insecticides or Fertilisers? XL ALL FERTILISER has pleased all who have used it this season. The Sales of XL ALL FUMIGATOR prove that it is more popular than ever. XL ALL LIQUID NICOTINE INSECTICIDE is always spoken of by gardeners and growers as the most deadly to Mealy Bug, Thrip, etc. XL ALL WINTER WASH for dormant Trees acts like magic, clearing the Trees and Bushes of all Insects' Eggs, Moss, and Fungoid Growths. XL ALL LAWN SAND, a weed eradicator and fertiliser for weedy and poor lawns. XL ALL WEED KILLER used once a year "No weeds can live." Please ask your Nurseryman, Seedsman, or Florist for a copy of my small pink list, giving particulars of these and many other XL ALL Preparations, which can be obtained from the Horticultural Trade throughout the World. G. H. RICHARDS, Manufacturer and Patentee, 234 Borough High Street, London, S.E.

TEN POINTS

IN FAVOUR OF THE NEW EDITION

...OF THE...

ENCYCLOPAEDIA OF GARDENING

By T. W. SANDERS, F.L.S., Editor of "Amateur Gardening."

1. Entirely new type.
2. New binding.
3. The inclusion of the species and hybrids in general cultivation, with description of their respective colours, height, time of flowering, native country, etc. This is a most valuable addition.
4. The breaking up of the solid nature of the text so as to make each cultural feature distinct.
5. The cultural notes have been considerably added to, especially those relating to vegetables and fruit and market culture.
6. The nomenclature of the genera has been thoroughly revised and brought up-to-date.
7. The cultural details are now given under the generic name only.
8. All the common names in general use have been included in alphabetical order.
9. There is no dictionary in existence which gives so much information on gardening in so small a space and for so little money.
10. It conveys in a nutshell all that the busy man requires to know about the cultivation and nature of any flower, fruit, vegetable, plant, tree, or shrub.

482 pages, bound in cloth. Price **3/6** net, from Booksellers: or by post, in box, 3/10, from the Publisher.

Published by W. H. & L. COLLINGRIDGE, 148 & 149, Aldersgate Street, London, E.C.

HANDY MAN wants SITUATION to assist Gardener; understands Bees (Certificated Expert). Can make the appliances, etc.; total abstainer. J. SHORT, 6, Freshwell Street, Saffron Walden, Essex.

HANDY MAN seeks SITUATION on Estate, Gentleman's Garden, or Nursery; wife Laundress, Poultry, or Help in House; well recommended. SANDERS, 2, Nelson Road, Gorleston-on-Sea.

LANDSCAPE GARDENER (22); six years' practical experience; good Draughtsman; seeks now or later Engagement; Trade or Private; good references. H. SAND, 6, Charles Street, Hillingdon Heath, Middlesex.

LADY recommends TWO LADS, ages 15 and 16, for Work in Garden; separate places; tall and good appearance; previous experience; to live in preferred; Church of England. Miss EDITH BROWN, The Priory, Little Waldingfield, Sudbury, Suffolk.

MESSRS. DROVERS highly recommend YOUTH, age 19, good worker, under the foreman for improvement; bothy. Nurseries, Fareham.

YOUNG MAN (20) seeks SITUATION in Garden; abstainer; strong and willing; three years' good character; left through reducing of establishment. Apply FRY, The Hut, Knightsbridge, Newbury.

YOUNG MAN seeks SITUATION in kitchen Garden or Kitchen Garden and Pleasure Grounds; good reference; age 23. Apply A. G. SLEET, The Gardens, Hatchford Park, Cobham, Surrey.

YOUNG MAN (27) seeks RE-ENGAGEMENT as Leading Hand in Kitchen Garden; leaving through reductions; used to duty, Bothy, etc.; good reference. A. E. FRENCH, 33, Spring Gardens, Northampton.

YOUNG MAN, 19, desires SITUATION as IMPROVER in Kitchen Garden or Pleasure Grounds; 4½ years' good character. Apply, A. ARGENT, Aldborough Hatch, Ilford, Essex.

PARISH OF SAINT LEONARD, SHOREDITCH.

COTTAGE HOMES, HORNCHURCH.

FOSTER-FATHER (GARDENER) AND FOSTER-MOTHER.

The Guardians of the Poor of the above-named Parish, invite APPLICATIONS from Married Couples (without children living with them preferred), for the APPOINTMENTS of FOSTER-FATHER and FOSTER-MOTHER, at one of the Cottages comprising these Homes.

The husband must be a Skilled Gardener, and he and his wife will be required to take charge of a Cottage capable of accommodating 32 Boys, and be competent, the man, to cultivate with assistance, extensive vegetable and flower gardens and to teach gardening, and the wife with the assistance of the Boys, to perform all the domestic work of the Cottage.

Salary, for the Foster-Father, £34, rising £2 annually to £42 per annum, and for the Foster-Mother £22, rising £2 annually to £28 per annum, together with board and apartments and an allowance of £3 per annum each, in lieu of beer should it be desired.

The appointments will be made subject to deductions under the Poor Law Officers' Superannuation Act, 1896.

Applications, upon forms to be obtained at my office as under, by forwarding a stamped addressed envelope, or by personal application, are to be sent in on or before WEDNESDAY, the 27th instant.

None but persons whose characters in all respects will bear the closest investigation need apply.

Further particulars can be obtained upon application to the Superintendent of the Homes, which are near Romford, Essex.

Canvassing the Guardians is prohibited, and will disqualify candidates.

By order,
ROBERT CLAY,
Clerk to the Guardians.

Clerk's Office,
213, Kingsland Road, N.E.,
January 18, 1909.

WARE'S
GOOD
ONLY
BEGONIAS

45 Gold Medals and Silver Cups Awarded. Premier Honour "Gold Medal" Franco-British Exhibition, London, June, 1908.

300,000 FINE LARGE TUBERS TO OFFER.

SINGLE, all colours, mixed, 2/6 doz.; 18/- 100. Separate colours, 4/- doz.; 25/- 100. Choice extra selected, 8/- doz. DOUBLE, all colours, mixed, 3/6 doz.; 25/- 100. Separate colours, 5/- doz.; 35/- 100. Choice extra selected, 12/- and 25/- doz. FRILLED-EDGED and CRESTED SINGLES, all colours, mixed, 6/- doz. Separate colours, extra good, 9/- doz. SPECIAL BEDDING VARIETIES: — Major Hope, Washington, Worthiana, Count Zepplin, Phosphorascens, &c.

BEGONIA SEED, WARE'S CHOICEST,
DOUBLE, mixed, 2/6 and 5/- packet.
SINGLE, mixed, 1/- and 2/6 per packet.

WARE'S HIGH GRADE
Vegetable and Flower
SEEDS.

Collections to give an ample supply of well selected Vegetables the year round from 10/6 and upwards.

Collections of Choice Flower Seeds from 2/6 to 60/-.

ALL SEEDS CARRIAGE FREE.

Burpee's
The Leading American Seed Catalog for 1909!

The "SILENT SALESMAN" of the World's Largest Mail-Order Seed Trade is a **New BOOK of 174 pages.** It describes Rare Novelties which cannot be had elsewhere, and tells the *plain truth* about the Best Seeds that can be grown—as proved at our famous FORDHOOK FARMS—the largest and most complete Trial Grounds in America. Handsomely bound in covers lithographed in nine colours, it shows, with the beautiful coloured plates (also in nine colours), Seven Choice Novelties in Vegetables, Three Superb "Spencer" Sweet Peas, and the most beautiful new Giant-flowered Pansies—all accurately painted from nature. With hundreds of illustrations from photographs and carefully written descriptions, it is A SAFE GUIDE to success in the garden, and should be consulted by everyone who plants either for pleasure or profit. While too costly a book to send unsolicited (except to our regular customers), we are pleased to mail it **FREE to every one** who *has a garden*, and can appreciate QUALITY IN SEEDS. Shall we mail You a copy? If so, kindly *name this paper* and **write TO-DAY!**

THE GARDENERS' MAGAZINE.

NOTES OF THE WEEK.

Old Age in Plants.

In connection with potatoes it is considered by some authorities that when a variety is propagated solely by its tubers for a long period, which means practically that its individuality is maintained throughout, it is apt to become weak in constitution, and therefore more liable to disease than it was originally. The implication is that a potato plant grows old, and that senility leads to death in the same way as in the animal kingdom. It is, however, somewhat of an open question whether this is really the case with perennial plants. Propagation by means of tubers, bulbs, or other similar accumulations in the soil of nourishment associated with buds, is practically much the same in principle as propagation by cuttings, inasmuch as no matter how extensively multiplication by this means may be carried on, or for how long, the entire result consists of parts of the original individual; and, taking a tree as an example, and imputing to this tree a normal life of a century, it would be natural to expect that by the end of a century all its parts would perish of old age. In point of fact, however, there is no definite evidence that mere old age determines the life of an individual plant at all. Death is brought about by other causes. In a tree the annual increase of its foliar system, laterally and perpendicularly, means a greater and greater risk of destruction by storms, which, if only partial, causes wounds, which are liable in an old tree to lead to decay of the internal wood, and thus to its eventual death. Given, however, such conditions of shelter as obtain in the region of the giant redwoods and eucalyptus, and we find evidence that the individual tree continues to grow healthily for many centuries. Given, too, such examples of longevity in trees which may be propagated by cuttings, and there is no doubt whatever that such cuttings could be struck with equal ease if taken now as when the tree was a sapling, and there is equally little doubt that, given like favourable conditions to those enjoyed for centuries by the parents, a young plant so raised would exist equally long, and so on practically ad infinitum. Tall, slender plants, such as palms, with a purely subterrestrial root system, have their life period determined by the fact that all their growth being upward, a time must come when the strain on the root system is too great, and, under stress of wind, they topple over; given, however, a tree fern, with a partly aerial root system springing from the frond bases, and, although subject to the same risk for the same reason, its summits could root where it fell, and so practically give it an entirely fresh lease, presenting again an indefinite life period in which senile decay plays no part at all. As a matter of fact, apart from annuals and biennials, the life period of vegetation seems quite indefinite, if we regard the entire plant as the unit, but in reality it is the leaf which is the unit, and in this we see exemplified within a comparatively short period, the several stages of youth, maturity, senile decay, and death. The plant itself, adhering to a tree as a typical example, is a community, a sort of commonwealth, which the successive generations of individuals, i.e., the leaves, contribute to create, support, and extend. There is no limit to the continued existence of such a community, unless, as we have seen, it is formed on such lines as to involve, sooner or later, a breakdown, coupled with no recuperative provision. The giant sequoia is a typical success, year after year, and century after century, it has judiciously buttressed its enormous trunk in proportion to its increasing altitude, a living pyramid of strength, while the palm we may cite as a typical failure through making no such provision. Turning back now to the humbler but far more important potato, we may see that grave doubts exist as to whether the decadence of varieties propagated asexually for long periods, is due to senile decay. May it not be partly due to faulty methods of storage and propagation?

MR. GEORGE J. INGRAM,
Secretary of the Gardeners' Royal Benevolent Institution.

Mr. George J. Ingram has, during the eighteen years he has occupied the position of secretary of the Gardeners' Royal Benevolent Institution, rendered such splendid service in the cause of charity in its relation to gardening, that we feel sure his portrait, which is given herewith, will be welcomed by a very large number of our readers. In briefly alluding to Mr. Ingram and his work, there is no occasion to write the history of the splendid charity with which he is associated, or to dwell upon the remarkable ability he has brought to bear upon the duties of his important office. These things are well known to the general body of horticulturists, but comparatively few may be fully acquainted with the enormous growth of the Gardeners' Royal Benevolent Institution during the period Mr. Ingram has been its secretary. Therefore, it may be of interest to state that when in 1891 Mr. Ingram was appointed, the annual income was £5,296, whereas last year it was over £9,000. During the same period the pensioners have increased from 156 to 224, and the amount disbursed in pensions has increased from about £2,500 to nearly £4,000. In addition, the Victorian Era Fund and the Good Samaritan Fund have been instituted, and from these, a sum of about £250 is annually expended in ministering to the needs of candidates awaiting election. Mr. Ingram is careful to avoid at all times claiming credit for the growth of the charity, but we know that the committee and other officers give him a very large share thereof, and very highly appreciate the zeal and judgment with which he discharges his exacting duties. We know also that he is very highly esteemed, and deservedly so, by the general body of horticulturists.

Cornish Gardens.—In the issues for February 6 and 13 we shall give an illustrated account of some of the more famous of the many fine gardens in Cornwall. The gardens that will be described and illustrated will include those of Bosahan, Pencarrow, Prideaux Place, Tregye, and Trevarrick.

Lilac Flowers in their normal colours have been steadily increasing in popularity for some years past, and the demand for them this season would appear to be larger than in any previous year. For a long period it was the practice to import the whole of the lilac flowers sent to Covent Garden during the winter from France, and these were invariably white. These flowers were not, however, those of one of the white lilacs, but of the common lilac, or of one of the two fine forms Charles X. or Dr. Lindley. The flowers of these when the plants are forced in a high temperature and a subdued light, lose their normal colour and develop white. Of late years the forcing of lilacs has been greatly extended in this country, and large quantities of the fragrant blossom in its natural colour, in addition to liberal supplies of white lilac, are annually sent to the flower markets. The soft colouring of the flowers of such varieties as Charles X. and Dr. Lindley, when developed with full exposure to the light and a moderate temperature, soon became popular for decorative purposes, and have been largely used for several years past. The French growers, quick to note the trend of public taste, turned their attention to the production of coloured lilac, and now send consignments to Covent Garden weekly, but the quality is not, as a whole, equal to the flowers of home growth.

A Profitable Garden.—The garden on the Brighton Downs, of which we have heard much during the past two or three years, appears to have produced exceptionally good crops during the past year. Originally three-quarters of an acre, the area was increased eleven months since to one acre and twenty rods. According to the statement of accounts the sum realised from the sale of produce was £105 10s. 2½d., and the expenses £18 8s. 11d., leaving a margin of profit of £87 1s. 3½d., without taking into account the vegetables consumed at home. The largest amounts received for the sale of produce were cabbages £11 11s. 11d.; cauliflowers and broccoli, £11 2s. 10½d.; potatoes, £9 4s. 10d.; and lettuces, £9 0s. 6d.; and the principal expenses were: rent, £5 18s. 6d.; seeds, £2 11s. 11d.; frame lights, £2 2s.; and manure £2 0s. 6d. The owner, Mr. Vincent, contends that with good cultivation a profit of £1 per rod can be made from garden ground, but with reference to this, the fact should not be overlooked that no allowance is made for labour. This being so, it would be more correct to say that £1 per rod can be obtained for the crops produced.

Winter Flowers in a Cornish Garden.—Mr. Howard Fox, whose beautiful gardens at Falmouth we described and illustrated early in 1908, writes: The recent cold snap must have spoiled the floral beauty of most English gardens, but it did not reach the south-west of Cornwall, so here they remain in very exceptional winter luxuriance. We have, for instance, at Falmouth the following trees, shrubs, and herbaceous plants flowering in the open air: Abutilon, Boule de Neige, 8ft. high; A. megapotamicum, 10ft.; Crusader, 8ft.; Prince of Wales, 10ft.; Acacia dealbata, 30ft.; A. longifolia, 20ft.; Acanthus mollis, Brugmansia lutea, 6ft.; B. sanguinea, 8ft.; Calceolaria amplexicaulis, C. Burbidgi, 5ft.; Citron, Madras, in fruit and flower on a wall; Clianthus puniceus, cyclamens in variety; Coleonema alba (syn. Diosma ericoides) has been showing flowers every day for the past two years; Cestrum elegans (syn. Habrothamnus fasciculatus); Cytisus prolifera, 12ft. high; Daphne vera indica; Desfontainea spinosa; ericas in variety; Eupatorium micranthum (syn. Weinmannianum), 10ft.; fuchsias, roses, and hydrangeas in variety; Melianthus major, 10ft.; Musa japonica (banana); Senecio grandifolia, Solanum Balbisii covered with orange-coloured spines, 6ft. high; salvias in variety; Sparmannia Africana, 6ft.

Loganberries are to supplant hops on the farm belonging to the Tunbridge Wells Corporation. Hops having failed to give a remunerative return, it was decided at a recent meeting of the Corporation to discontinue their cultivation and to devote the land now occupied by them to the loganberry. A commencement will be made with three hundred plants, and if the results should prove satisfactory the cultivation of this fruit will be extended.

Fruit Culture around Wisbech.—The Board of Agriculture and Fisheries have been supplied with some carefully compiled estimates of the production of the fruit crops in the neighbourhood of Wisbech, and the following summary of them is given in the current issue of the Board's "Journal." The ordinary rent of farm land is put at £2 per acre, while small occupiers of selected land adapted for fruit growing and conveniently situated may pay from £2 10s. to £4 per acre. In a few instances large farms occupied by old tenants are rented for less than £2 per acre. There is not a great difference in the rent of medium-sized fen farms and those on silt land. A good crop of strawberries is estimated at three tons, and a moderate crop at half that amount. An average price is £17 per ton. From full-grown gooseberry bushes a return of six to eight tons is regarded as a good crop, and of two to three tons as a moderate one. These are valued at £9 a ton. Plums in this locality are generally grown round the orchards near the dykes, chiefly for shelter, but an acre of mature trees might be expected to yield five tons at £6 a ton, while a more moderate crop would produce three tons. As regards apples from full-grown trees, ten tons an acre should be secured in good years, and about half this quantity in less favourable seasons. The price would be about £7 a ton. Bramley's Seedling would possibly yield much more on a good soil, while choicer and more delicate kinds would produce less. Owing to the variation in seasons, age of trees, and kinds of apples, it is difficult to arrive at an average.

Flowering of Gooseberries in 1908.—Mr. Cecil H. Hooper points out the need for careful records of the flowering dates of various fruits, the state of the weather at flowering time, the duration of the flowering period, and the amount of the crop. This he does in the current issue of the "Journal" of the Board of Agriculture, in an article to which we hope to refer again. He shows that at Wy gooseberries began to flower on April 15; by the 19th about a quarter of the flowers were open; on the following night there was a frost of 10 deg., with slight snow, and again when nearly in full bloom on the nights of the 24th, 25th, and 26th they were subjected to frosts of 8, 5, and 2 degs. respectively; on the first night there was snow, which apparently protected the blossoms, as they did not shrivel and fall as might have been expected. Birds (probably house sparrows and chaffinches) "snibbed" many blossoms near the farm buildings between April 15 and 25. The bushes were in full bloom from the 28th to May 1, and continued in flower till May 13, the flowers at the tips of the boughs being the last to open; by the 21st the flowers and berries that had been pecked by birds had fallen. The duration of flowering from the opening of the first flowers to the closing of the last was thirty-six days. Picking the green berries commenced on May 26, about a month after full flower. The crop was good, the picking was done by going over the bushes three times with intervals between. The weight of fruit on one good bush was 21lb. The first ripe gooseberries were picked on July 10, the fruit from a good bush of Yellow Roughs weighing 14lb. The different varieties of gooseberry in the plantations appear to flower at nearly the same time—Lancashire Lad, Berry's Early Kent, and Whinham's Industry, commencing to flower in the order named.

Importation of Gooseberry and Currant Bushes.—The Amendment Order of 1908 (No. 2), which came into operation in December last, provides that the American Gooseberry Mildew (Prohibition of Importation of Bushes) Order of 1907 shall not apply to the landing of any currant bush under the authority of a licence authorising such landing obtained from the Board of Agriculture, nor to any bush so landed. A penalty not exceeding £10 is imposed for irregular dealing with imported bushes, and a power of entry is given to inspectors of the Board of Agriculture or of the local authority appointed under the Destructive Insects and Pests Acts, 1877 and 1907. If on examination an inspector finds any bush which is affected with American gooseberry mildew (Sphaerotheca mors-uvae) he is to prohibit the removal of any gooseberry or currant bush from the premises.

Polypodium Mandaianum, one of the most recent of the exotic ferns introduced to cultivation, has the promise of proving a valuable addition to the ferns suitable for conservatory and house decoration. It originated with Mr. W. A. Manda of New Jersey, and at the National Flower Show held in America a short time since was awarded the gold medal for the best new plant in commerce. We have no information as to its parentage, but the fronds are tall and arching, and the pinnae are of great breadth and deeply cut, in much the same manner as are those of the fronds of the Welsh polypody.

PROTECTION OF FRUIT BUDS FROM BIRDS.

At this season of the year the visit from the bullfinch becomes assertive where there are gooseberry and other fruit trees, to whose buds these birds are so partial. Various means are devised for protecting the buds, and probably the best that can be adopted is an enclosure of wire netting, but as this is not admissible in every instance of fruit culture, other practices have to be adopted to effect the desired object. There is much that can be said in favour of wire netting, because, not only can the buds be made safe, but the ripening crop also, for it is well known that much trouble comes in summer when such fruits are exposed to native birds. Especially are gardens much visited by fruit-eating birds when they happen to be located near extensive woodlands, for then not only are local-bred birds in evidence, but they apparently invite their feathered friends from a distance.

Various scares are devised, but they have not much permanent effect; indeed, when the weather is very dry the blackbird and thrush are actually bold enough to allow joint gathering from the same tree. In such cases fixed or moving scares are not of much effect, and nets must be well placed, and free from broken meshes, to make the crop secure from their raids.

At the present time the safety of the buds is uppermost in most gardeners' minds, and it behoves those who are usually victimised, if they have not already taken steps to repress their attacks, to make early preparations. We do not know what may be the actual reason, but usually we find no mischievous inclinations on the part of bullfinches until the new year has commenced. Probably there are sufficient privet or other berries in the woods and hedgerows to satisfy them until that season, and possibly, too, the swelling up of the buds makes them more attractive to the eye and pleasant to the palate of these birds. In town gardens sparrows are even more destructive than bullfinches, and early measures have often to be taken to prevent them doing much damage.

Some cultivators pin their faith on soot and lime dustings, which perhaps sometimes serve the purpose very well; in showery weather it needs to be applied often, and it may be said other remedies necessitate some degree of repetition. Quassia extract is a favourite of others, while petroleum emulsions have long been regarded as important in bud protection.

Since nicotine has entered so largely into the prescriptions employed in the garden, one does not wonder it has been utilised in the protection of gooseberry buds. It was by accident that we came to regard this with much favour for the purpose of winter spraying. Having used a nicotine emulsion on some fruit trees quite early in the season as a preventive of red spider, we were surprised to find that an offensive odour had been imparted and that it remained a considerable period. This experience suggested that bush gooseberries exposed to the raids of birds might be protected by a spraying with the emulsion. With knapsack pump one annual spraying is now given, and since the first use of nicotine emulsion we have not had much anxiety for the safety of these trees. It would appear to be so extremely nauseous that a little goes a long way, and especially when these economical spray pumps or an Abol syringe is used for applying the liquid.

Beside acting as a deterrent of bud-eating birds, it has another very material value—a red spider exterminant—and in some gardens this insect is very insidious in its attacks on gooseberry trees. Last summer, after the crop had been gathered in a green state, nicotine emulsion was applied to a small plantation of gooseberry trees here which had become rather seriously infested with red spider. The results were magical, for not a living "spider" could be found a week later when an inspection was made. Thus trees that are remembered to have been injured last year with red spider may be advantageously dressed with a two-fold object. We therefore advise those who may have the dual worry incident to winter bud-eating birds and summer attacks of red spider to give nicotine emulsion an early trial. Fresh slaked lime may still be used in cases where birds have been kept in abeyance with its aid, dusting it on while the branches are damp Only new lime becomes permanently adhesive.

GERANIUM IBERICUM PLATYPETALUM.

GERANIUM IBERICUM PLATYPETALUM.

There are over one hundred species of geraniums known to botanists, including a dozen native of Britain. Perhaps none are more worthy of a place in the flower border than the one of which I send a photograph. It is a strong-growing perennial, attaining a height of two feet or more; the flowers are of a deep violet colour, beautifully striped with red, and measure over an inch in diameter. The stems are densely clothed with prettily-lobed leaves, fringed at the margin. It is at its best about midsummer, and affords a bright patch of an unusual colour for a considerable time. It is native of Georgia, and is somewhat larger in every respect than the type.

Cambridge Botanic Gardens.

NEW HARDY TREES AND SHRUBS OF 1908.

The number of hardy trees and shrubs, exclusive of roses, which have received either first-class certificates or awards of merit from the Royal Horticultural Society during the year 1908, show a decided falling off from the preceding year, when three first-class certificates and fifteen awards of merit were given. The numbers for 1908 are two certificates and but eight awards of merit, whereas in 1906 there were nine awards but no certificates. It is very interesting to note how the numbers fluctuate year by year, and one frequently notes a "fat" and a "lean" season alternately.

When referring to the lists of awards for the last few years one cannot fail to note the important part that Mr. E. H. Wilson's travels in China on behalf of Messrs. Veitch have played in the introduction of new trees and shrubs, for in 1907 the three first-class certificates and four of the awards of merit were obtained by his plants, and in 1908 the only two certificates and two of the awards of merit were made in favour of plants sent home by the same collector.

To the readers of the Gardeners' Magazine these new trees and shrubs will be by no means unknown, as not only is a full description given at the time the award is made, but lifelike illustrations of some of the principal ones have appeared in these pages during the past year, viz.: Viburnum Carlesi, on April 24, page 323; Deutzia Wilsoni, June 20, page 473; Ilex Pernyi, September 19, page 715; and Populus lasiocarpa, October 10, page 763.

A complete list of trees and shrubs receiving awards in 1908 is given below:

Viburnum Carlesi.—A very pretty member of the extensive viburnum family, and one, I should say, destined ere long to become a general favourite. It is a native of Corea, but was first brought prominently forward by Messrs. Boehmer, of Yokohama, Japan. In the autumn of 1905 it was distributed by MM. Lemoine et fils, of Nancy. This viburnum belongs to the deciduous group of the genus, and the leaves, which are more or less pubescent, are somewhat like those of the Wayfaring tree (Viburnum lantana). In general appearance the flowers, borne in rounded terminal heads, suggest those of some of the rondeletias. The buds are reddish, but when fully expanded this tint, being on the reverse of the petals, is hidden, and the expanded blossoms are then pure white. Individually the blooms are larger than those of the Laurustinus (Virburnum tinus), of a thick wax-like texture, and very fragrant. An award of merit was given to this viburnum on April 14. The specimen appeared to have been brought on under glass, but on May 9 a specimen out of doors at Kew was flowering beautifully in the open ground despite the severe weather experienced about a fortnight before.

Azalea occidentalis graciosa.—The Temple Show rarely passes without one of the many beautiful hardy azaleas there exhibited being selected for an award of merit. This variety, which was so honoured in 1908, is a very free-flowering variety, whose large, fragrant blossoms are in colour white, with yellow markings in the two upper segments. In the bud state the flowers show just a suspicion of rose.

Philadelphus Lemoinei Rosace.—One of the finest of all the beautiful varieties of Philadelphus Lemoinei. The flowers are comparatively large, and semi-double. They are decidedly suggestive of a small rose, and in colour white. This variety possesses the pleasing fragrance of many of the forms of Philadelphus Lemoinei, a fragrance inherited from one of its parents, namely, the little P. microphyllus. An award of merit was given to it on June 9.

Rhodothamnus Kamtschaticus.—A dwarf-growing ericaceous shrub, nearly related to the rhododendron; indeed, it was at one time included in that genus. It is of a deciduous nature, and forms a somewhat spreading shrub about a foot high, clothed with hairy leaves, ovate in shape, and an inch or a little more in length. The comparatively large solitary flowers are about 1½ inches across and of a deep rosy-purple colour. In general appearance they very much suggest those of the Himalayan Rhododendron lepidotum. This rhodothamnus is of wide geographical distribution, being found in the northern region of both hemispheres. Award of merit June 9.

Deutzia Wilsoni.—One of the many new deutzias that we have received from China during late years, through the medium of the collector whose name it bears. It is certainly a very promising species, and forms a sturdy bush, clothed with deep green lanceolate leaves. The pure white flowers are borne in both terminal and axillary spikes for a long distance along the shoots, and when the strongest of these arching over with their weight of blossom are at their best, it forms an exceedingly charming and graceful shrub. Award of merit June 9.

Erica cinerea pygmæa.—Our own native Grey Heath, Erica cinerea, is represented in gardens by numerous varieties, whose blossoms vary in colour from white to deep red. This dwarf form, much less in stature than the type, is also remarkable for the brilliant tint of its crimson blossoms. Award of merit June 23.

Coriaria japonica.—A very pretty shrub, which is seen at its best in the southern part of this country. It is of a low, spreading habit, and though the flowers are not at all showy they are succeeded by berry-like fruits, which first take on a reddish hue, finally deepening to dark purple when ripe. This coriaria was given an award of merit on July 21.

Ilex Pernyi.—The first tree or shrub to be given a first-class certificate in 1908 was this dwarf-growing member of the holly family. The general opinion is that this honour was well deserved, as it is a decidedly pretty little evergreen, and one likely to become popular, especially for small gardens. It was introduced from China by the Messrs. Veitch, through their collector, Mr. E. H. Wilson. It is of dense compact habit of growth, the leaves being from 1in. to 1½in. long and closely set on the branches. Each leaf is oval in general outline, but it has usually two prominent spine-tipped teeth at each end, and a long, tapering, sharp pointed apex. The berries are much like those of the common holly. The general aspect of the foliage much suggests a small form of another Chinese holly—Ilex cornuta. First-class certificate, September 1.

Populus lasiocarpa.—A new Chinese species of poplar, particularly remarkable for the large size of its leaves. They are broadly cordate in shape, and as shown on young plants are about a foot long by ten inches or so in width. The footstalk and prominent veins are bright red, and thus stand out conspicuously against the deep green of the rest of its leaf. It is said to form a fine tree, 50ft. or so in height, and, judging by appearances, its growth will be rapid. It is very possible that if this poplar be cut down annually, as is often done in the case of the ailanthus, paulownia, etc., it might prove of great value for sub-tropical beds. First-class certificate, September 15.

Sarcococca ruscifolia.—The sarcococcas constitute a small genus of evergreen shrubs, natives of the Himalayas, Afghanistan, and surrounding districts. They belong to the natural order Euphorbiaceæ, and their nearest relatives, from a botanical standpoint, among hardy shrubs, are the different forms of box. Sarcococca pruniformis, a somewhat tender shrub, was introduced as long ago as 1820, and with this species Sarcococca ruscifolia has been previously confounded. It is, however, now considered to be distinct, and an award of merit was given it at the meeting of the Royal Horticultural Society on December 22. As shown it is a dwarf evergreen shrub, with shining, bright green, pointed leaves. The flowers, borne in small clusters in the axils of the leaves, are whitish and fragrant. They are succeeded by small berries, which are said to be of a bright blue colour when ripe. W. T.

WATERING PLANTS.

One very important factor in the successful culture of plants in pots is the right use of the watering can. It would be difficult to lay down any definite laws on the subject, and still more to find those who would carry them out if laid down. Watering has to be regulated to a great extent by local circumstances, also by the requirements of the different kinds of plants under treatment. More mischief is done at this time of the year by over-watering than by insufficient watering. This is particularly the case in regard to fern culture.

It is a common idea that all ferns require to be potted in peat, heavily shaded, and drenched with water, but many of our most tender ferns may be grown fully exposed to the sun, potted in loam and kept rather dry than otherwise. It is after repotting that they are most liable to suffer from too much moisture. If the new soil besomes sour before the roots have taken hold of it they will not make a good start, but after the pots are well filled with roots they will take and need more water. Yet either extreme should thus be avoided.

With all flowering plants the evil of over-watering is equally apparent. Various subjects, of course, require different treatment, and just at the time they are in full bloom they take up much more water than previously, without regard to the pots being fuller of roots than at the earlier period, and many fail to flower satisfactorily if only once allowed to become too dry, after the buds have set. Take camellias for example, I believe there are more buds lost through drought than any other cause, though keeping the house too warm for a few days and then lowering the temperature again will prove equally disastrous. Poinsettias and Euphorbia jacquiniaeflora are both very liable to lose their roots through either extreme. The result is more frequently seen when the soil is too wet; yet, at the same time, it may be caused through being too dry in the first place.

During winter plants standing on a moist base will require comparatively little water, while those on a dry stage, specially if there are hot-water pipes beneath, are liable to dry at the bottom while the surface may appear moist.

Ashwellthorpe Gardens.

PILLAR ROSES.

Pillar roses form a delightful feature in the garden when planted in suitable positions, and given the attention necessary to ensure the full development of their distinctive characteristics, and are usually much admired by visitors. This admiration is largely due to the fact that roses suitable for training to pillars are sparingly grown, and not always with the success one could wish. That these charming roses should not be planted in larger numbers and cultivated with a full measure of success is difficult to understand even by those who are familiar with their peculiarities, and with what is being done in gardens in the matter of rose growing. Sometimes the results are more or less unsatisfactory owing to the use of rampant varieties that are only suitable for pergolas, for climbing tall trees, for flinging their long, slender growths over rough supports in the wild garden, and in other positions where they can grow unrestricted without the risk of injury to roses and shrubs generally of moderate growth. Roses of more moderate growth than the ramblers are the best suited for pillars, especially when, as in many cases, they are associated with dwarf bushes and standards.

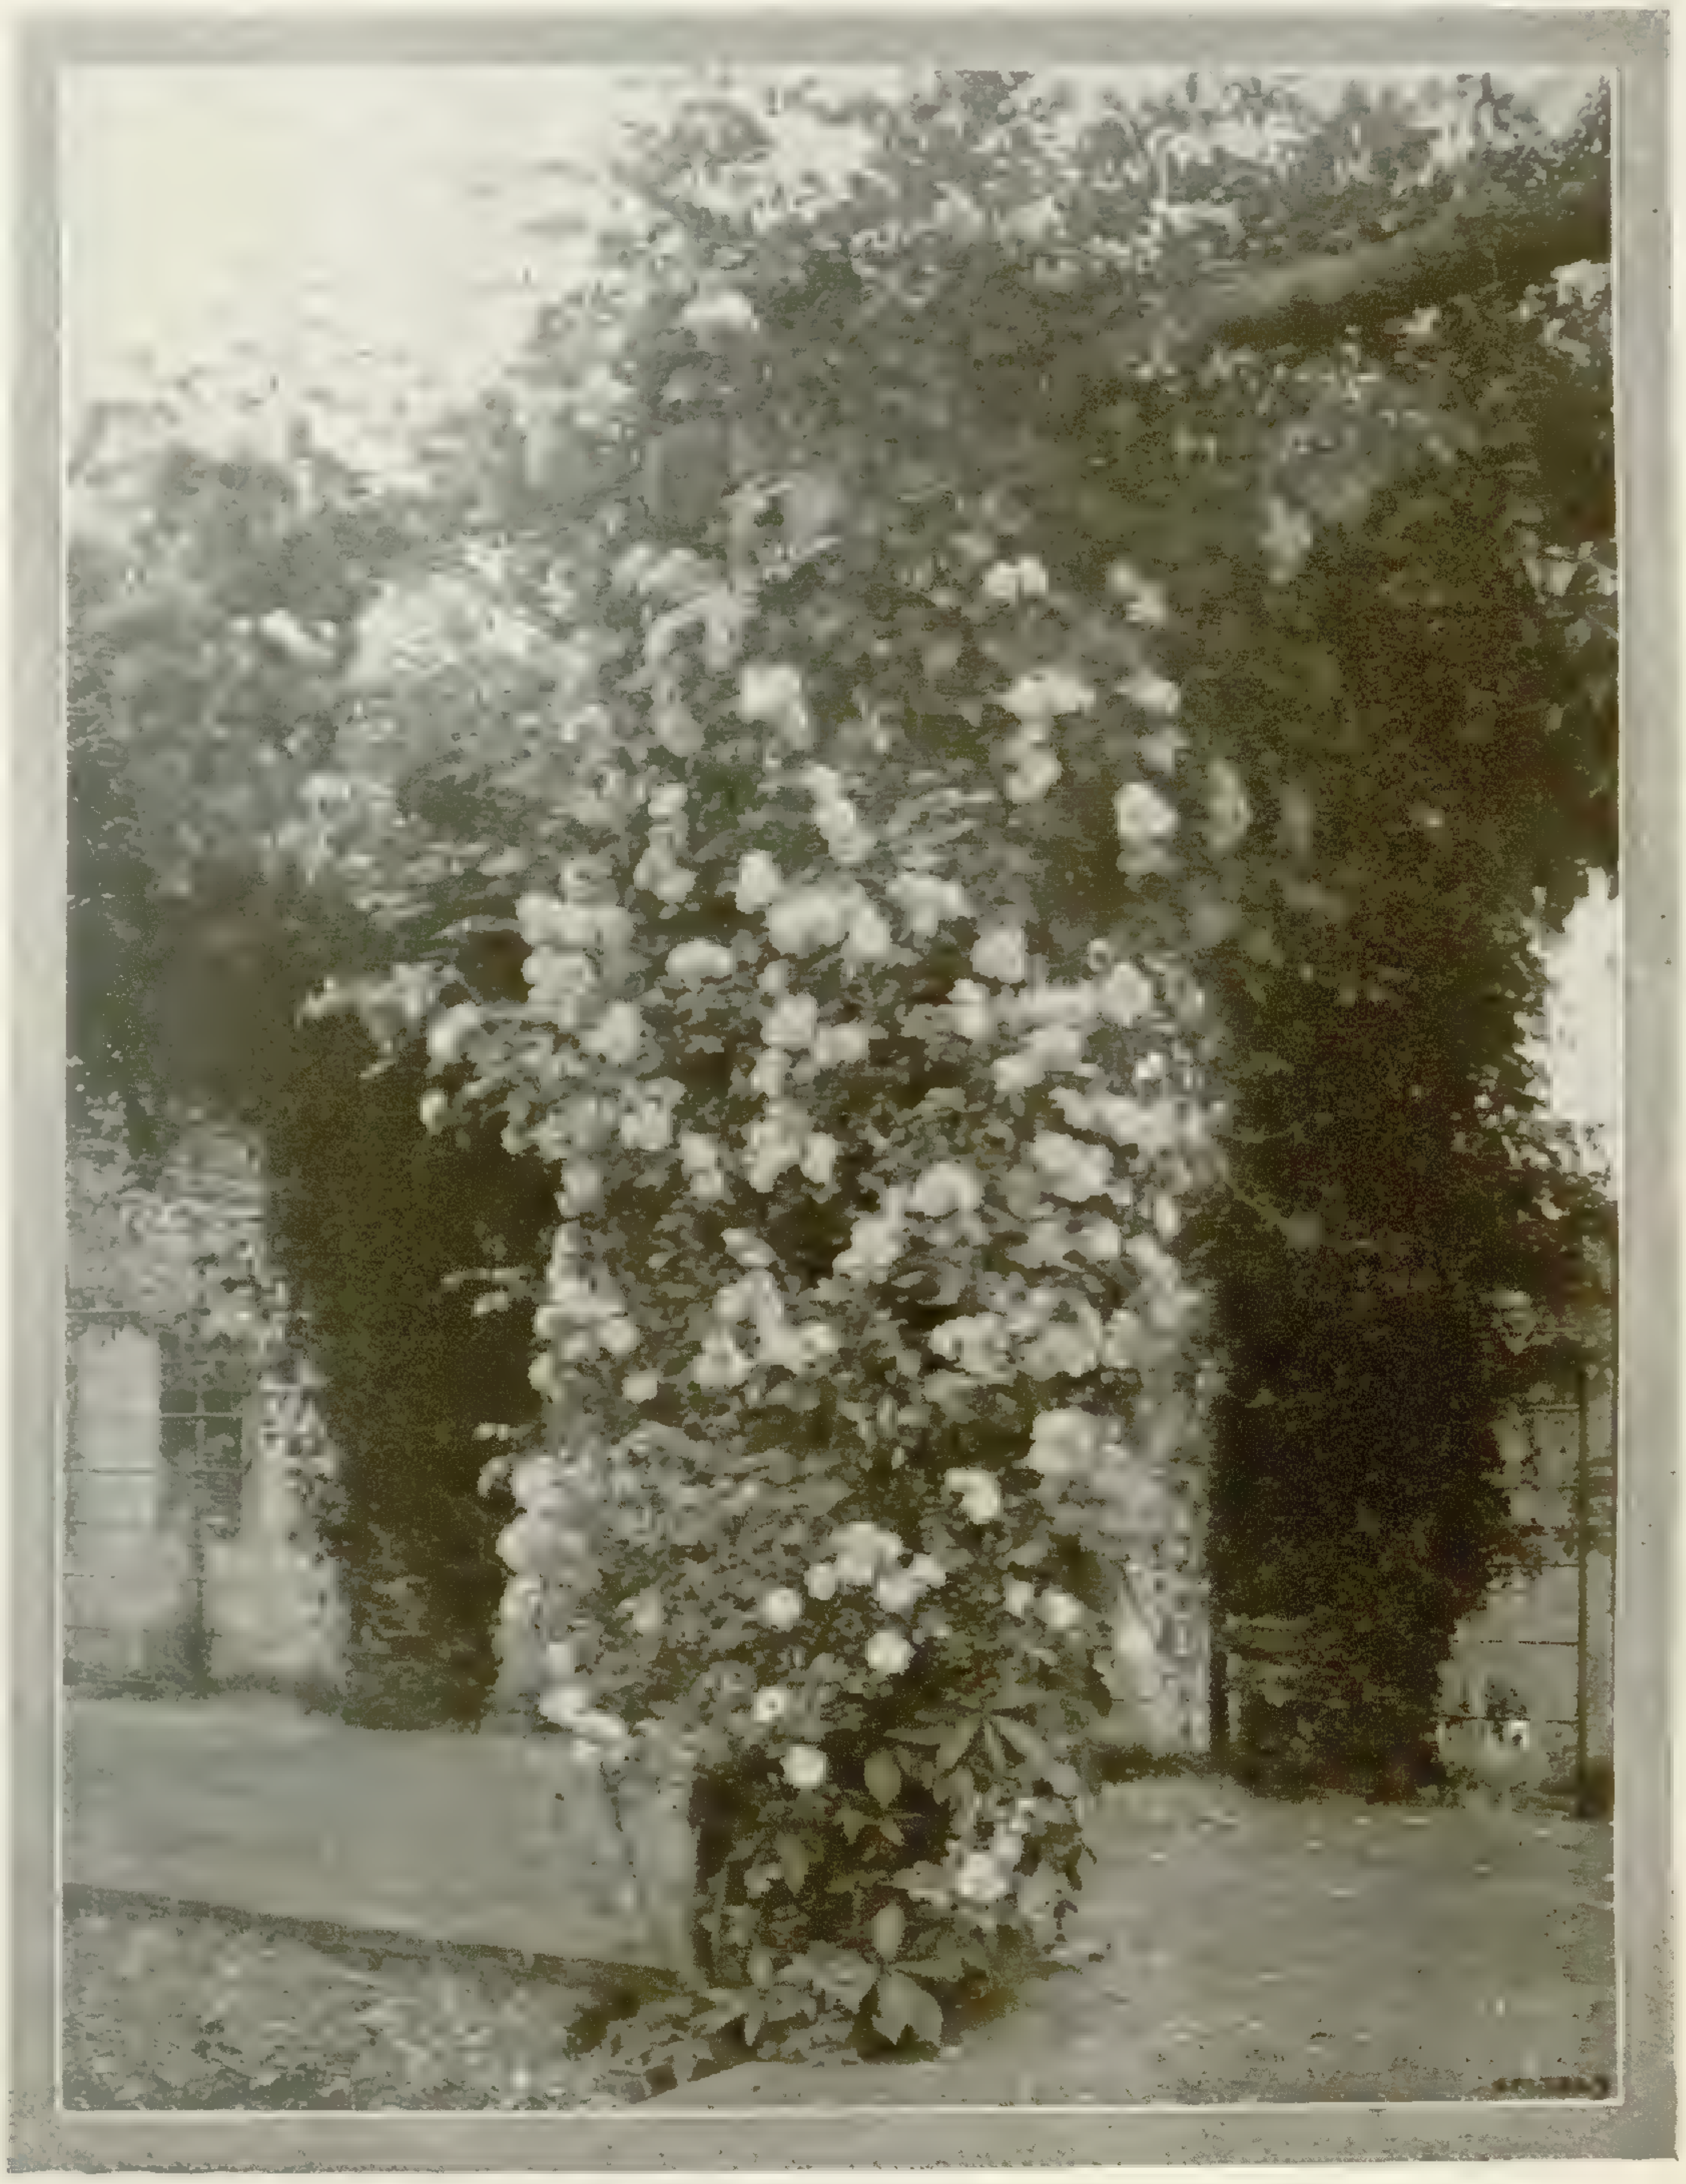
Varieties that will, under ordinary good culture, reach the top of pillars ranging from seven to nine feet high in two years, should, as a rule, be selected. As a guide to the planter the following may be mentioned, as especially desirable: Alister Stella Gray, Ards Pillar, Billiard et Barre, Climbing Mrs. W. J. Grant, Dr. Rouges, Francoise Crousse, Gruss an Teplitz, Leuchtstern, Madame Berard, Madame Alfred Carrière, Madame Pierre Cochet, Psyche, William Allen Richardson. The foregoing varieties present a pleasing appearance when trained to larch poles from four to six inches in diameter. Unfortunately, these poles decay at the base in the course of a few years, and there is a risk of the pillars being blown over when well furnished. The iron rods sometimes recommended and used for the support of roses of this class do not afford a sufficient training space, and for this reason I much prefer the admirable rose pillars manufactured by Messrs. Barnard and Bishop, of Norwich. They afford plenty of space for training the growth, and there is no risk of their being blown over.

There is no occasion to deal in detail with the management of roses trained to pillars. Like other roses of vigorous growth they prefer a soil that has been liberally manured and deeply dug previous to planting. It is therefore a good practice to mark out the station for each, and spread partly rotted manure from the stable or farmyard over the surface to a depth of six or seven inches; then stir the soil with spade or fork to a depth of two feet, and well incorporate the manure with it. As a matter of course, the planting should be done during the season of rest, and the soil should, when being filled in about the roots, be trodden very firmly. It is a good practice to cut the shoots back to within a few inches of their base in the spring following the planting. Frequently, the lower portions of pillars present a somewhat bare appearance, but this may, to a large extent, be prevented by a simple course of procedure. When the main shoots are shortened in the spring, instead of fastening them to the pillars, bend them down, and make secure to short stakes. Allow them to remain until the lower buds are well started, and then train to their permanent supports. This will necessitate additional work, and great care in handling, but the improved results will be ample compensation.

Viator.

PRIMULA FORBESI.

Old plants of Primula Forbesi that have done service in the greenhouse during the winter should be retained for planting out in the open some time during March or April, choosing a half-shaded border or part of the rock garden where they will continue to produce a bright display during the summer months. The baby primrose, as it is commonly called, is, to some extent, overshadowed by the innumerable florists' forms of the Chinese primula, nevertheless, it is an ideal subject for amateurs to flower in small pots in the greenhouse during winter.



ROSE ELECTRA, TRAINED TO A BRICK PILLAR
In the Gardens of East Burnham Park.

Early in August these old plants are lifted and divided, single crowns are placed in pots 2½ inches in diameter, using a light rich soil. For a month or six weeks afterwards they are grown in a cold frame, suppressing all flower spikes as they appear. About the first week in October the plants are removed to the greenhouse, and from this time forward they are encouraged to develop their flower spikes. Very soon the flowers begin to unfold, forming, when fully developed, perfect miniatures of blossom. The distinct value of small pots is now apparent, as it admits of their use in table decorations, and endless means can be found for employing them indoors in filling bowls of porcelain or filigree, either alone or when associated with ferns or small palms as foliage subjects.

Primula Forbesi is easy to raise from seed sown in small pots of carefully prepared soil; the seed is sown on the surface, and the finest covering of soil applied, and the pots have small sheets of glass laid over them to retain the moisture till germination takes place. When the seedlings are large enough to handle they are pricked into thumb pots, and grown in a cold frame throughout the summer months: those from spring sowing will flower in summer, while seeds sown at the end of May will give strong plants to bloom in winter.

The flowers of P. Forbesi bear a strong resemblance to our native Bird's E'en (P. farinosa) in colour, as also in the distinctive marking around the mouth of the corolla tube, while in the leaves it resembles the hardy Chinese species, P. cortusoides. The flowers are produced in successive whorls, and the slender stems and tiny leaves are coated with a white farinose powder, giving the plants a silvery appearance. It is a native of Yunnan, China.

"CHRYSANTHEMUMS AND HOW TO GROW THEM FOR EXHIBITION," by J. B. Wroe. Fifth Edition, revised to January, 1908, and including the new varieties.—Full details on timing and stopping for Northern, Southern, and Midland growers, selections of the best varieties, illustrated instructions on taking the buds, cuttings, staging, etc. Prices 1s. net, by post 1s. 2d.; cloth, 1s. 6d., by post 1s. 8d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

FLORAL DECORATIONS.

In the arranging of cut flowers, as in every branch of art, tastes differ widely, and not only so, but styles approved yesterday are often condemned to-day, and that not simply by the spread of refinement among the mass of the people, for it is said that not many years ago the decoration of royal dinner tables usually consisted of a combination of fruit and flowers, whereas now such a method is generally discountenanced.

A generation ago, when the use of cut flowers in the house was, comparatively speaking, in its infancy, it was quite usual to go round the garden and pick a variety of flowers pretty much as they took one's fancy, afterwards putting them all together in an upright vase, only giving such attention to the arrangement as was necessary to avoid the actual crushing of the flowers; and such a method, even to-day, is by no means uncommon in the houses of the middle-classes, especially where material prosperity has increased faster than the appreciation of the beauty of form and colour. Still, in the houses of people of culture and refinement—an ever-increasing class—this method, or want of method, has disappeared, and there has been a general movement in favour of floral arrangements consisting of only one or two different kinds of flowers, with some greenery, preferably that belonging to the flowers it is put with, or to one of them.

It is said that the origin of this latter fashion is in part owing to the Japanese, whose arrangement of flowers, though altogether conventional, has been studied and systematised for so long and in such detail that Josiah Conder's great book on the subject is properly called "The Floral Art of Japan." The essence of the Japanese system of floral arrangements is extreme economy in the use of material, and, to the stranger's gaze, apparent simplicity, though in reality every blossom, leaf, and twig, conform to certain ancient rules of relationship to the other blossoms, leaves, and twigs of the composition.

The limitation of variety in floral arrangements which has found favour with some of the best judges in this country of recent years has been justified and upheld as being a return to Nature, who never gives us incongruous juxtapositions, and its supporters say that if in arranging flowers we were to try and imagine how they would be placed in a state of Nature we could not go far wrong. Nature never puts a dozen different kinds of things on a piece of ground six inches across, or sets side by side geraniums and maidenhair fern, carrot leaves, and begonias, seakale leaves and dahlias, etc.

However convenient it may be sometimes to resort to some of these unnatural associations, it did seem as if this school of floral artists was founded on unassailable principles. But such a belief can no longer be held. Two profusely illustrated books on floral decoration were issued from the Press in 1907 by well-known writers and acknowledged authorities upon their subject, and many, if not most of the illustrations in both books represented mixed arrangements of three or four, or even more, different kinds of flowers. As photographs, or copies of photographs, the illustrations were certainly very beautiful, and doubtless the originals from which the photographs were taken were beautiful also, for the flowers were arranged by those who had made a life-long study of the subject, both as regards beauty of form and the blending, harmonising, and contrasting of various shades of colour, and were doubtless irreproachable from both points of view, and to those who know nothing of flowers in other than the cut state would be quite satisfying. But not so to the man who loves the flowers when growing more than when cut, who has studied their different habitats, and to whom a flower taken out of that habitat is a flower divorced from the setting Nature made for it. To such a one, mixed arrangements, unless of flowers one sees naturally associated together, give no pleasure, while the unnatural associations in anything but wreaths, buttonholes, and other confessedly artificial and conventional forms, are little less than a desecration.

We must consider the merits and demerits of mixed arrangements in the two-fold aspect of colour and form. As regards colour only, mixed arrangements made by someone possessing a thoroughly trained eye may be a perfect poem if we can disregard the flowers as individuals and simply regard them as so many dead bits of colour, or dummies. Regarded from this point of view only it may have greater richness, and may be a greater feast to the eye than a simple bowl of roses or sweet peas. But to those who love both flowers and Nature in general such arrangements can only give pleasure in so far as they are to some extent a reproduction of associations that may be met with in the garden or in wild Nature, always assuming that the garden is planted with due regard to colour effect. We know what pleasure is often derived from unlooked for associations in the garden. I had an instance last year in a self-sown scarlet nasturtium running over a clump of pale lilac-blue Michaelmas daisies and there is endless scope for colour effect in the various colours of sweet peas, chrysanthemums, dahlias, etc., so that it is not necessary to a colour scheme to put a dozen different kinds of flowers into one receptacle.

Moreover, apart from the dissatisfaction it may give to a true Nature lover, one needs to be very sure of the truth of one's sense of colour, or one may be setting up a composition giving great satisfaction to oneself but positive annoyance to someone with this sense more highly cultivated. People with small gardens often want to make them a museum of varieties with only a plant or two of each, with the result that one can only get enough to fill a good-sized vessel by mixing a number of kinds together. Here is a dilemma which the owners of such gardens must settle for themselves according to their tastes.

As regards form, the same general remarks apply to some extent; but though one may learn from a book that certain colours go well together and others do not, yet, the recognition of beauty of form, and still more the capacity to produce it, can only be obtained in their fulness by long continued observation. It is obvious that if a dozen different flowers are to be put in one receptacle the arrangement must be a very large one indeed if the individual items composing it are to have the opportunity to display their full beauty of flower, leaf, and stem. It is in this respect, perhaps, more than from the point of view of colour effect, that small arrangements are to be preferred, and this is the great study of the floral decorators of Japan. If a vessel is filled with flowers of the same species—not necessarily of the same colour—their beauty of form, by reason of different pieces of the same plant revealing different points of beauty, will have a much better chance of making itself felt than if there were a dozen or more kinds of flowers in the same receptacle, when, even if the individual flowers have the chance of fully displaying their full beauty, the effect produced is that of general indefiniteness, leaving no distinct impression upon the eye, as so many sermons leave no distinct impression upon the mind for the same reason.

To sum up then in conclusion, my idea is that simple arrangements of one or two kinds of flowers are more likely to give general pleasure than more elaborate arrangements, the latter often giving no satisfaction to the real garden lover, while sometimes, by reason of the ambition of those arranging them outstepping their powers of performance, they may even offend better-trained eyes, either by reason of their unhappy colour effect or concealment of the true beauty of the flowers employed.

Alger Petts.

THE CATALPA.

This tree is still mostly a stranger in our gardens, though there are many fine specimens which have been established for years in different parts of the country. It is difficult to overestimate the value of this noble tree, it has so many advantages that were one in the unhappy position of having to plant but one tree in the grounds, it would scarcely be possible to select a better!

Two others run it very close, but the catalpa would always be one point ahead, on account of its late period of flowering, in the second or third week of July and on during August, at a time when there is no other large mass of blossom to be looked for. The manner of flowering superficially recalls the horse-chestnut, but the blossoms themselves are far daintier and more lovely, being quite orchid-like, and delicate in appearance and colouring. The leafage retains its pure clear green to the last, and grows old gracefully, remaining on the branches, with one exception, longer than that of any other tree. This would make it invaluable, but besides this, it has in its favour the size and beautiful form of the leaf, the contrast of this in its unchanging spring green, to the dark wood of trunk and branches.

The distinctive growth of the whole tree and its late period of flowering make it the most desirable of all the trees, even for towns, where it thrives amazingly, and has there a value all its own amongst its darkened, withered, scorched, and leafless fellows. It possesses, in fact, but one drawback in that it makes a late start in spring, and at that time of year does not show the cheerful pale greenery which is one of the chief charms of spring; this, however, is to its own advantage, as it otherwise might be harmed by the late frosts.

Some trees do not lose very much by being set in close company with others. The catalpa, however, is pre-eminently one that needs a good prominent position, not only on account of its individuality, but to allow it to develop its shapely limbs and produce uniformly the wonderful blossoms. It is a quick grower, and flowers when about fifteen years old, and never attains a very great height, generally only about 30 to 40 feet.

It may be planted in most positions, preferring, however, a moist soil.

E. Curgwen.

MANURE HEAPS.

Whether the advent of motor vehicles and their extended use will ultimately cause the manure heap to vanish cannot be said, but in three or four cases with which I am familiar the motors have certainly reduced the number of horses required. I think all gardeners should, so far as possible, encourage foxhunting, because the attendant large stud of hunters required provides much grand garden manure, indeed, no better manure is made than where a large number of hunters are kept.

The horses are always well cared for and much straw is used for bedding purposes. Of course motors will materially lessen the number of carriage horses required, but they will not supersede the horse for riding and hunting purposes.

In very large places the manure is carted from the stables every morning, and it is usually taken to a stockyard where horses, cows, oxen, pigs, poultry, etc., work among it and convert it into rotten manure for the farm, and, of course, as much for the garden as the gardener requires. But the land agent or steward naturally does not like too much of his manure to be carted to the garden, for he has never enough for farm purposes. It is useless, however, for a gardener to try and produce good crops from the same old garden year after year unless he adds a plentiful supply of manure. In large establishments the preparation of the manure rests with the farm men, and the gardener simply fetches the finished article, well rotted, and to use a familiar phrase, "it cuts out like butter."

In smaller establishments the care of the manure heap generally rests with the gardener, the stablemen cart or wheel it out and leave it, and the garden men turn it to induce rottenness. One of the chief points to be observed is to not allow the manure heap to become very hot, as great heat from fermentation engenders dryness, and it also kills the manure, indeed, if a considerable quantity of manure was tipped in a heap and it became hot, the lower portion would become dust dry and would never be fit for use. A common error in the preparation of manure is a wet position; the site for a manure heap should be chosen where all superfluous water can be drained into a receptacle of some sort to be used as liquid manure. A well drained stockyard should always have a large underground tank to receive all drainage, and this should be pumped out and used by a liquid manure distributing cart, or in some other way.

The manure heap should be turned often, and when stacked to be prepared for use make the heap about 4ft. wide, 2ft. 6in. deep, and, of course, the quantity will regulate the length. Manure from the stables, with careful attention, should be ready for use in ten or twelve weeks. For many crops manure in a newer state can be used, but I am writing of rotten manure. I am a great advocate of a very large manure bed for gourds, vegetable marrows, and gherkins, and the bed should be dug out about 4ft. 6in., or 5ft. wide, and from 1ft. 6in. to 2ft. deep, and any length convenient. Into this hole any vegetable matter may be tipped during the winter, and in May this should be topped with stable manure and the marrows planted and grown on it. After the frost has killed them in the autumn the manure can be used for various purposes in the garden, and the pit is then ready for the same course of action each succeeding year.

One way of securing good manure for the garden that used to be practised had much to recommend it, and that was when rhubarb and seakale beds were covered with leaves and stable manure mixed, to cause a gentle heat to force rhubarb in tubs and seakale in pots. The same plan does not obtain now in many places, as the respective roots are lifted and forced in heated frames or houses, and nowadays the old manure heated frame is not so common as it used to be, so the gardener's sources of supply are to some extent restricted.

The commercial value of rotten stable manure in our district is now 4s. 6d. per ton; about ten years ago an advance of 6d. per ton was made, the former price being 4s. per ton. The very great anxiety to obtain manure from stables in large towns by farmers, market gardeners, etc., who make a practice of loading in to market with produce, and fill their lorries, carts, etc. with manure for the homeward journey, makes it appear very plainly that the humble manure heap plays a very important part in our gardening business. It is a question of great importance to gardeners and farmers whether the very large quantity of land in the British Isles that is now laid down with grass is not against their best interests, for really the cereal crops with the grand straw they produced were the backbone of really good farmyard manure, and no amount of peat moss litter, sawdust, tan, or any other sort of bedding will ever equal good straw in making a good and serviceable manure heap.

Cheshire.

LILIUM LONGIFLORUM.

Although Mr. W. H. Page, of the Tangley Nurseries, Hampton, has become famous as a cultivator and exhibitor of perpetual-flowering carnations, it is well-known that his activities include the growth of various lilies on a very large scale for the production of flowers for market. In the growth of lilies Mr. Page is not less successful than he is with carnations, and visitors to the exhibitions and meetings of the Royal Horticultural Society will have a lively recollection of the magnificent vases and stands of these flowers that usually form part of his collections. On the 12th inst., three effective arrangements of lilies in bamboo stands were shown by Mr. Page in addition to a beautiful display of carnations, and it affords us much pleasure to give an illustration of the fine stand of flowers of Lilium longiflorum giganteum, which formed the centre-piece of his attractive exhibit.

LILIUM LONGIFLORUM GIGANTEUM.
A magnificent stand of this fine pure white lily, exhibited by Mr. W. H. Page, at the R.H.S. Meeting on January 12.

COLOUR EFFECTS IN THE FLOWER GARDEN.

Concurrently with the increase in the popularity of hardy plants, mixed borders have assumed a position in the flower garden of commanding importance, and in consequence thereof their planting and management calls for the exercise of much taste and great skill. In bygone days, when hardy plants were relegated to an unimportant position, the chief points the cultivator had to consider were selecting a position where they would enjoy the light and air essential to their health and provide a suitable soil. Now, something more has to be done. Positions have to be selected for the borders where they will best fit into the general scheme of the garden and contribute the most liberally to its interest and attractiveness. The conditions must, it need hardly be said, be favourable to a vigorous growth, and the plants should be arranged in the border with due regard to the production of an effect that will at once appeal to the eye when the border is being inspected, wholly apart from its surroundings. For example, the plants should be so arranged that they will occupy positions in the border relative to their height that will prevent a suggestion of flatness or formality, and also the plants of low stature being hidden from view by their taller neighbours. Due regard has of necessity to be paid to the flowers, as well as to the growth, and care taken to produce as far as is possible harmonious colour effects.

In the planting of borders, where the garden is of limited dimensions, the practice so general of including a diversity of colours in the same border is undoubtedly the best. It certainly enables the owner to enjoy a greater diversity of form as well as of colouring than is possible when the selection is limited to plants bearing flowers of one colour. This is so obvious that there is no occasion to labour the point; but it can hardly fail to prove useful to point out that in borders in which there is a wide range of colours a much more tasteful effect is produced when the colours are spread with a bold hand, than when they are so distributed as to suggest that they had been sprinkled with the aid of a loose brush. Not only is it desirable to adopt a bold style of planting for the purpose of obtaining striking colour effects, but the scheme is far more pleasing when the plants of the same or closely-allied kinds are so arranged as to give prominence to their distinctive habits and foliage.

Where the flower garden and pleasure grounds are of sufficient area to afford space for several borders, in addition, a pleasing innovation upon the old practice may be made by limiting one or more borders to plants producing red, blue, or white flowers, according to the taste of the owners. In several gardens that we have had the pleasure of visiting the planting of borders with distinctive colours has been carried out with much success. White borders would appear to be the most popular, the ratio being, according to our observations in different parts of the country, three borders of white flowers to one border of red or blue flowers. It is simply a question of taste. We should place blue first, red second, and white third, but we would advise planters to follow the bent of their own mind in deciding which of the colours they will select if they are not able to have more than one or two.

The finest of the red and blue borders that have as yet come under our notice are those in the gardens of Hillingdon Court, Uxbridge, the residence of Lord Hillingdon. These have the advantage of being spacious and of having been judiciously planted, and with the aid of the accompanying illustrations it will not be difficult to realise their extent and beauty. One of the finest of the examples of planting with white flowers that we have seen was in one of the many fine gardens in the vicinity of Norwich. It is only in large gardens that spacious borders, such as those illustrated, can be devoted to separate colours, but a feature of a quite charming character can be obtained in borders of quite small proportions, provided they are kept well apart.

THE RED WALK, HILLINGDON COURT.

[Photo: H. N. King.

In the blue border at Hillingdon Court Anchusa italica Dropmore variety, violas, lavender, delphiniums, and lupins are prominent, but there would be no difficulty in having a comparatively large and varied selection, if so desired. Among other blue-flowered plants of special excellence are aquilegias, asters annual and perennial, campanulas, dracocephalums, echinops, erigerons, eryngiums, galegas, gentians, geraniums, iris in great variety, lithospermums, mertensias, polemoniums, scabiosas, stokesias, and veronicas. In the planting of red borders the example that has been set by Mr. Allan, the head gardener at Hillingdon Court, should be followed, and roses be very largely planted. Varieties of great excellence, with red flowers, may be selected from the hybrid perpetuals, hybrid teas, teas, and dwarf polyanthas. The association of standards and dwarf bushes, as in the Hillingdon Court border, is essential to the production of a pleasing effect, and a few pillar roses trained to rustic poles may be introduced if considered desirable. If a border more varied than would be obtained by roses alone is required, herbaceous pæonies, carnations, hardy heaths, pentstemons, Oriental poppies, pyrethrums, hardy fuchsias, should be freely selected from. Carnations, it should be remembered, consort admirably with roses, and red stocks and asters, which are readily raised in large quantities from seed, will also be useful, as will dwarf cannas with soft red flowers. In the association of miscellaneous plants with roses care must be taken to arrange them in such manner that those of strong growth will not injure the roses. G.

THE BLUE WALK, HILLINGDON COURT.

The Lawrence Medal.—In the year 1906 Sir Trevor Lawrence, Bart., completed the 21st year as president of the Royal Horticultural Society, when the Fellows, as an expression of their appreciation of the services he had rendered the society, decided to found a gold medal to be known as "The Lawrence Medal." The funds necessary to give practical expression to this decision were subscribed within a comparatively short period; and, after full consideration and some unavoidable delay, the execution of the work has been entrusted to Mr. Bertram Mackennal, the well-known medallist.

AMONG THE ROSES.

On looking over our roses since the frost I find they have come through the ordeal much better than might have been expected, more especially when we consider the excessively keen wind that prevailed. A keen wind appears to do much more harm during a severe frost than does a frost of greater severity with a still air, and this is most marked upon newly-planted roses and the hedge briars for standard stocks. It is very trying to the last-named, because they have no roots with which to draw up supplies of moisture from the soil, and, consequently, the cells become dried up. I often think that we might do better by protecting these a little more. In the first place, the stocks are taken from the shelter of hedgerow or copse, have had almost the whole of their roots cut off, and are not much more than a sucker roughly removed from a stub of old growth. With scarcely any root, and fully exposed to the open, it is surprising they do so well.

After the frost and wind it will be advisable to examine the beds, and tread the plants up firmly, and where the frost has partially raised them they should be pressed down to their original position. Cuttings of roses are often drawn up as much as two or three inches at these times, and need pressing down before the roots start from the callus that has already formed.

At any time now, according to the condition of the soil, the ground may be dug over very lightly. One great advantage of digging is the ease with which one can use the hoe early in the season to keep down seedling weeds. Some growers have a strong objection to digging among their roses, and I do not advise the spade to be inserted its full length. Three or four inches is the depth we favour, and the ground is turned over as roughly as possible.

Where planting has still to be done I would recommend deferring it until the middle or end of February, unless the ground is in a very favourable condition. By that time, moreover, one can see where the beds need filling up, and with the influence of sun and a little warmer soil the roots will begin to run freely at once. One can fill up vacant spaces until May with plants from pots.

It is too early to prune, except one has a number of roses upon walls or arbour which necessitate a considerable amount of work just at a time when so many things demand urgent attention. A great deal of this work can be done now by thinning out the old wood, and it is well to take advantage of quiet days before we are overpressed in other directions.

This is a very busy time under glass. Pruning should be completed now, and a little higher temperature afforded as the season advances. Steady forcing is preferable. It is astonishing how quickly the plants will respond to a moderate temperature as the sun gains power. A slight check after too hasty forcing is the cause of many blind or flowerless growths. Another frequent cause of this comes from using insecticides of too great a strength, sometimes in fumigation, and sometimes in solution. That pearl among white roses, Niphetos, is very apt to lose its tips of growth and buds through these causes, and

I have frequently lost a quantity of very young growths through this, and the roots being a little too dry. A judicious use of the syringe and light fumigation, alternately, is more beneficial than a strong application of either remedy by itself. Liquid manure from the cow stall has proved the best with me for pot roses. Ventilation needs very great care at this season, and not much is required until March. The long rods of Marechal Niel and other climbers will be pushing into new growth, and we often find these secured too closely to the glass roof, with the result that many of the flowering shoots are against the glass before the buds form, and so suffer from extremes of temperature, which often completely spoil the crop. Eighteen to twenty-four inches is none too far from the glass, as all young growth is certain to draw that way. A. Piper.

PEARS NOT KEEPING.

At page 911 of last year's volume of the Gardeners' Magazine is an article on pears which appears to be somewhat out of place, as the varieties your correspondent mentions are usually in December pretty well all finished. For example, Emile d'Heyst is an October-November pear in the south and west. Marie Louise belongs to the same period, Doyenne du Comice is a November pear, but from a south wall, in a good season, the fruit will be ripe at the end of October, and can be hastened by placing in heat. The fruits, however, are not so good as when allowed to hang on the tree till they are really fit for gathering. I have kept Doyenne du Comice till December 10, but the fruits must be kept very cool to remain in good condition so late. Charles Ernest is another pear that is much in evidence in the month of November, and I do not think it is better at any time than in the last fortnight of November and the first week in December. Catalogues are sometimes a little misleading with regard to the season in which pears attain maturity; but with experience and observation this can soon be put right. It will be noticed that most all of the leading growers place Charles Ernest and Doyenne du Comice first in the list for November and December, but in the south and south-west it is impossible to keep either of these in perfect condition till Christmas. Glou Morceau, Hacon's Incomparable, Nouvelle Fulvie, and Winter Nelis are the best varieties for the dessert at Christmas. With regard to apples, I have not found that these are keeping badly. Of course, the early varieties are sure to go off when their season is over, and there are so many varieties that are in season in October and the early part of November, and in a mild season they apparently appear to go off quickly.

Leonardslee Gardens. W. A. Cook.

Saxifraga Rudolphiana. — The greater number of the saxifrages of the oppositifolia section have one common failing, which renders them less useful than they should be for our gardens. This is the difficulty of inducing them to flower freely in cultivation for any number of years if left alone. This is particularly noticeable with some of the larger varieties of S. oppositifolia, and it is frequently necessary, if much in the way of flower is wanted, to tear the plants to pieces occasionally, and to replant them. Sometimes they will even grow bare and unsightly in the centre if left alone. I have found, when I grew it some years ago, that S. Rudolphiana, which belongs to this section, and which, I consider, should not have specific rank, is less troublesome in this respect, and I found that it would go on longer without this operation of splitting up, or, rather, tearing to pieces, than its allies. It is also earlier than S. oppositifolia, and a better bloomer, generally covering itself with fine flowers of a rosy purple. It grows only two or three inches high.—S. Arnott.

IMITATION IN GARDEN PLANTING.

The "sincerest form of flattery" is a mistake when carried to excess in garden-planting; we all visit our neighbours' grounds as well as our own, and have little pleasure in finding them very similar; if the same plants are better grown than in our case we are naturally pained; if they are worse grown our satisfaction can be at best a base one. Come out of a rhododendron shrubbery into one of hawthorns, and the change is a lesson as well as a delight. Study a tea rosery after rambling among the home hybrid perpetuals, and a new pleasure is gained. Turn from flat geometrical beds to a display of perennial-filled ones, and the contrast is as instructive as charming.

In the gardens of large estates there are usually some noted or striking features, but the rest of the arrangements follow upon conventional lines; in villa gardens even this originality is seldom achieved, and whether trees, shrubs, bedding, herbaceous or annual plants are considered they will be found of the ordinary kinds, set in familar style. There is especial reason to regret this uniformity in the case of front gardens, because the whole aspect of our country and suburban roads would be glorified by a brave abandonment of old combinations and methods. The speculative builder receives most of the blame for the tame character of front plots, but in truth the leaseholders and purchasers are far more culpable, since the trees and plants that have been put in to give something of a cultivated effect are easy to move either for rearrangement or abandonment. It is not that the shrubs, etc., are ill-chosen so often as that they are not used boldly. Take the golden elder as an example, as a hedge along a boundary it presents a grand appearance, yet it is never seen except as a squeezed specimen among other specimens, firs, laburnums, hawthorns, lilacs, etc. A laburnum row against a railing would be so uncommon as to constitute a noted show each spring, but who cares to observe or comment upon the single laburnums that are dotted along roadways, one in each garden?

An old author has stated: "Floriculture differs from kitchen gardening in one grand principle—that whereas the latter has no free-will in the choice of the objects of its care—for whether in Great Britain, or Australia, in Russia or in Italy, a gentleman's household must be supplied with all possible, as well as all necessary vegetables and fruits. The flower gardener enjoys a wide range, and liberty of selection, which makes a failure on his part incalculably more discreditable."

No doubt the commonplace planting we witness is just the result of a species of greed, the desire to have a lilac if the next-door neighbour has one, also a double crimson may to match his, as many hybrid perpetual roses, a rockery covered also with aubrietia and arabis in spring, beds similarly gay with first wallflowers, then pelargoniums, and, if possible, a few more tulips and calceolarias, edged by crocuses and lobelia. The lesson to be learnt is not to covet all flowers, but find greater content in perfect culture of a very few.

The same ancient writer gives this advice, in chatty form: "What style of garden shall we have? To what branch of horticulture shall we give our attention? On which group of the vegetable kingdom shall we spend our money? How shall the exterior of our villa residence look from without and within? Shall we form a little arboretum, and nestle ourselves beneath a cluster of some dozen or twenty rare hardy trees? Shall we go into the Dutch line and gratify our taste for florist's flowers? Shall we make a rosery, and be content to look a little naked in the winter if we can but have a blaze of bloom during summer and autumn? Any of these proposed plans can be carried out in villa gardening; only there must be no indecision, no patch-work, half-measures, nor coalitions of opposite aims and principles."

Is there anywhere in England, I wonder, a sunny front garden given up to the cultivation of lilies with pansies and violas? The Crown Imperial and the "Lent lily" might be allowed to appear before true lilies, and masses of the crimson scarlet Schizostylis coccinea, could be permitted to yield brilliant blossoms in November. Surely such a style of planting, if well carried out, would be renowned for more miles than can be estimated? A garden of white roses chiefly would be a delightful one in front of a new red-brick villa; a few dark-foliaged evergreen shrubs would be needed to form an effective background, the carpeting plants could be mostly white-blossomed also.

A semi-shady front garden given up to woodland or wild plants might be scorned by a vulgar few, but would gratify the artistic tastes of innumerable passers-by. Foxgloves, single roses, honeysuckles, Myosotis palustris, various orchids, daffodils, bluebells, blackberries, Solomon's seal, mulleins, ranunculuses, calthas, primroses, and violets should appear in it.

> "Many such there are.
> Fair ferns and flowers, and chiefly that tall fern,
> So stately, of the Queen Osmunda named:
> Plant lovelier in its retired abode
> On Grasmere's beach, than Naiad by the side
> Of Grecian brook, or Lady of the Mere,
> Sole-sitting by the shores of old Romance."
> —Wordsworth.

It is even rare for the rosery to occupy wholly the front garden, yet in many cases this would be far more suitable than locating it behind the house, losing thereby the best sunshine and aspect. Lastly, it should be more realised that flowering trees will flourish among lower-growing shrubs; a thicket of rhododendron can be partly overhung by acacias, Berberis aquifolium by laburnum and double peaches and cherries, laurustinus by almonds. M. H.

Daphne Mezereum grandiflora.—This distinct variety of the common "Mezereon" is worth planting in every garden where winter-flowering shrubs are encouraged, for it possesses a lengthy flowering season, and is at its best a month in advance of the type. It is a very old garden plant, although it is difficult to obtain in the present day in quantity, and was mentioned by Loudon nearly seventy years ago, under the name of autumnale or autumnalis. This synonymous name was probably given on account of its habit of opening some of its flowers in autumn. The blossoms commence to open in October, and a few continue to expand throughout November, December, and early in January, the majority opening rather rapidly towards the end of the latter month, and continuing until March. In colour they are very similar to those of the type, whilst they are equally fragrant and larger. The whole plant is more vigorous than the type, the wood being stronger, and the bush of larger dimensions. It is increased by grafting on stocks of the type, but is not one of the easiest shrubs to deal with. Two-year-old wood is often better for scions than that formed in the previous summer.—W. D.

THE FERTILITY OF SOILS.

All land that can be worked at all can be made fertile, and that to a degree above the present indifferent average. Poor land can be made sufficiently rich if treated in an intelligent manner, and the experiment is well deserving of some effort, even when accompanied with some risk.

This question of fertility may be viewed in several ways. The essence of fertility is to have two forms of soil in the right condition. These forms are organic and inorganic. No crop can be produced from either separately, and when they exist together, there must be the right conditions of warmth, air, and moisture to enable them to be of use to the growing plant. In the absence of either organic or inorganic matter fertility cannot exist, and even then the surrounding conditions must be suitable. Without the inorganic material we lack the matter and the body; failing the organic part we are without the force. With the two under suitable conditions there can be built up a substantial crop.

Inorganic matter is by far the greater portion of most soils. It is the dead part of the soil. If soil be burnt the organic part is got rid of, but the inorganic remains. An ordinary piece of rock or stone is wholly inorganic. It will not burn. Coal, on the other hand, has much organic matter as is known by the amount which can be burnt from it and the difference in weight between a piece of coal and a piece of coke. To ascertain the amount of organic or inorganic matter in a soil, place a sample in a place where it will become quite dry. Then weigh 100lbs., or 10lbs., and burn it. Weigh the ash that remains and the difference will show the amount of organic matter in the soil.

Although inorganic matter is the dead matter of the soil it must not be supposed that its necessity and usefulness can be ignored. It plays its part in the composition of crops quite as effectively as does the organic portion. The one gives life and motion, the other substance and support. It must be understood that a plant can only assimilate food in a soluble or liquid form, and the chief object of cultivation is to assist in dissolving both organic and inorganic matter.

Organic matter is an essential part of a fertile soil, for without it no crop can grow. All cultivable soil contains organic matter, though not always in an available form. This is an important distinction and touches a fundamental principle of fertility. A soil may contain much matter which goes to the make-up of the proposed crop, and yet be unable to support that crop. It may seem paradoxical to assert that fertile land may not be productive, or that unproductive soils may possess the elements of fertility. That this is the case has been proved by chemical analyses. A soil which has been unable to support a full crop has been tested by expert analysts and found to contain plant food of the kind required, and far in excess of what would be needed for an average crop. The analysis of a soil is no criterion of its productiveness unless such a statement shows how much of the plant food is ready for immediate use by the plant.

A safe and simple method of ascertaining the value of a soil would be to collect from various quarters of a plot an average sample of soil. Tie this in a thin muslin bag and put it to soak in clear rain water. After a few days the water should be analysed. This would show roughly the amount of plant food which is soluble and thus ready for immediate use, for it must be borne in mind that the root-hairs of the plant can only take up food in a liquid state. The value of a soil can only be rightly gauged by distinguishing between the plant food which is active and that which is inert.

The organic or vegetable and animal matter in a soil is often spoken of as humus. Besides affording plant food humus acts beneficially in a mechanical manner. It imparts a dark colour to the soil, and thereby in some degree helps to absorb and retain sun-heat. It keeps the soil open, and thereby obviates the danger of stagnation. It is capable of absorbing water in much the same way as a sponge, and is thus of considerable advantage to a dry soil. It opens the soil to the influence of air. It makes the soil proportionately less weighty. It also serves as the happy hunting ground of myriads of little organisms which perform the task of converting plant food into a form such as can be beneficially used by the crop. Without humus in the soil the proportion of these organisms would be considerably reduced, and the crop thereby have less food for assimilation.

DECORATIVE CHRYSANTHEMUM, MAUD ALLAN.
Exhibited by Mr. N. Molyneux at R.H.S. Meeting, January 12, when an A.M. was made in its favour. Flowers much reduced; pure white.

That lime is of value as a plant food is disputed by some, but that it is of great use in bringing the soil into a state of fertility is acknowledged by all, though not sufficiently appreciated by practical cultivators. Lime has the property of rendering the organic matter fit for immediate use. It accelerates the decomposition of manures, and thus brings into use at once food which might have remained inert for a considerable time. But its effect is not confined to organic matter, for in combination with the mineral portion it forms many useful salts. It is chiefly known and used as a corrective of sourness due to a superabundance of manure. If lime is freely used and a good crop taken from the land there is little fear of the soil becoming sour. In fact, heavy manuring, heavy cropping, and frequent liming should go together. In gardens where initial outlay is an important factor less manure could be used one year and the money thus saved invested in lime.

Lime is essential to fertility, and is usually found in all soils, but, as with manure, it is used up by continuous cropping, and if the supply is not kept up the quality and quantity of the produce will suffer. Especially is lime needed when through exigencies of space the same land has to have the same class of crop drawn from it year after year. The available plant food required by that especial crop becomes used up, whilst there is a superabundance of matter which cannot be utilised. Lime will in such a case counteract the acidity of the unused plant food and bring more food into a fit state for the plants' nourishment. In fruit culture lime is most necessary, and its judicious use tends to considerably reduce the ravages of insect and fungoid pests.

WILLIAM F. ROWLES.

NEW PLANTS, ETC.

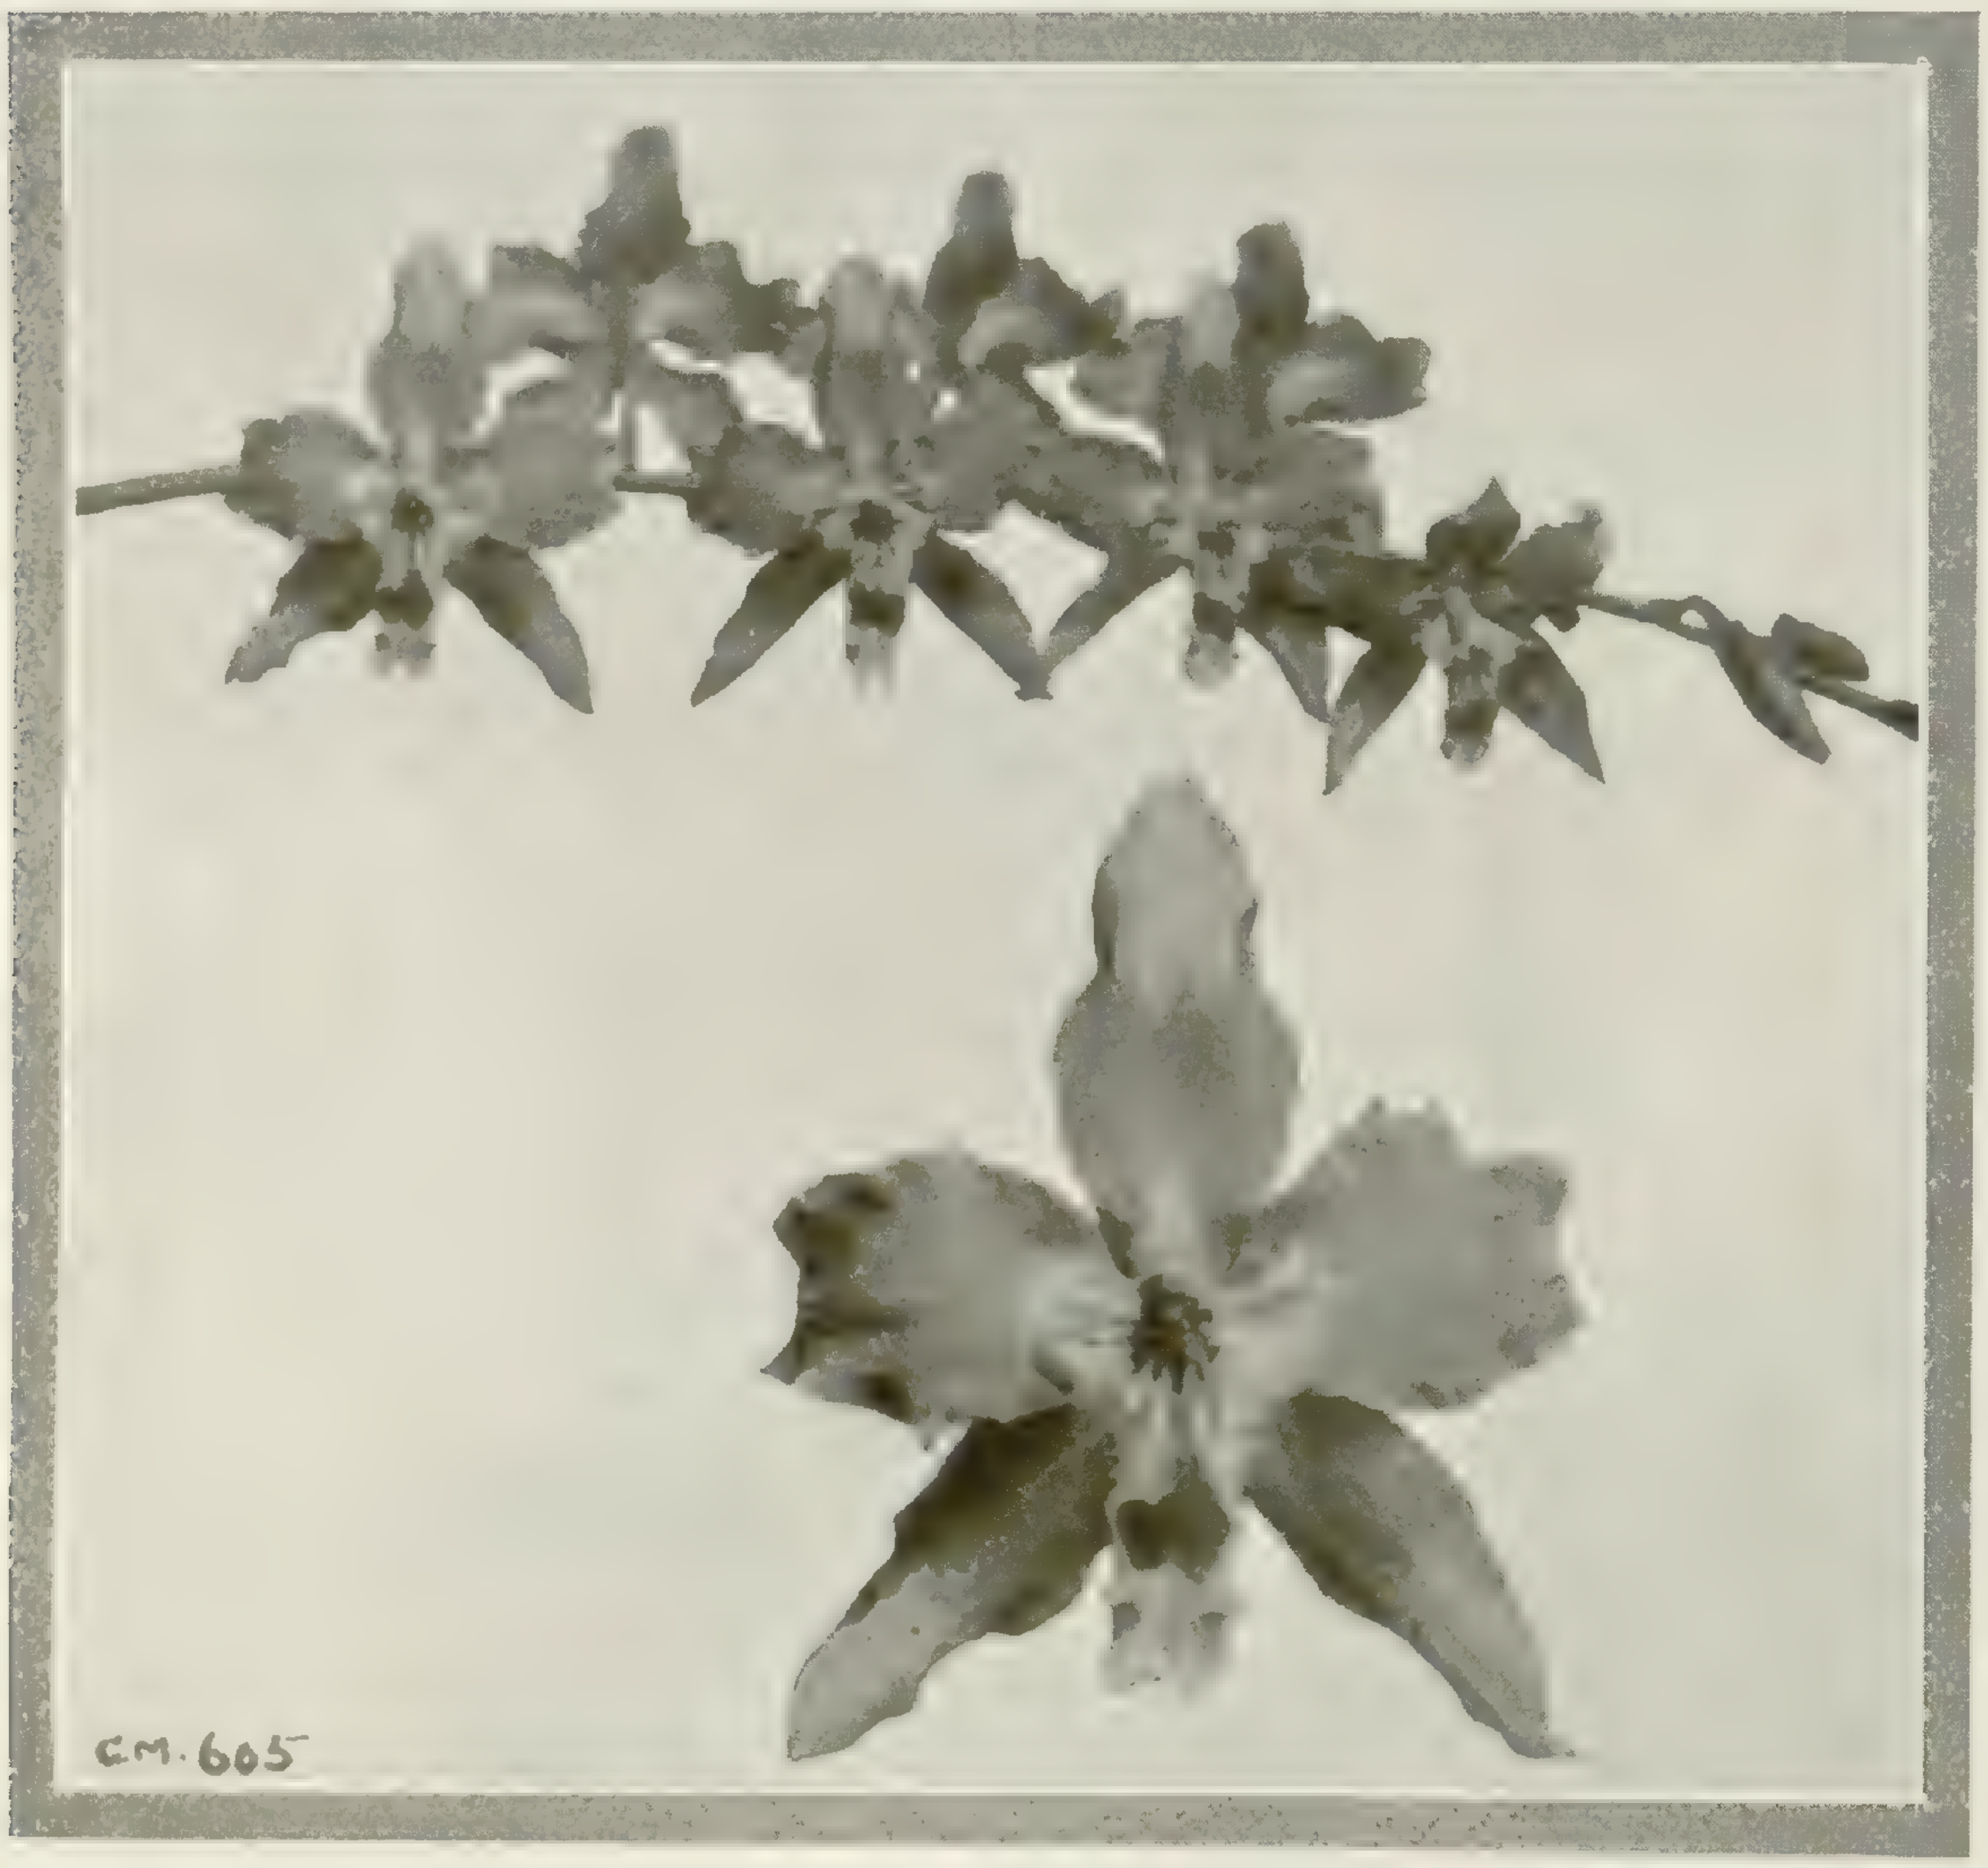
◆

CHRYSANTHEMUM MAUD ALLAN.

A distinct Japanese variety of much value for decorative purposes at midwinter. The blooms are pure white, comparatively small, but full, and with narrow, slightly revolute florets. A.M., R.H.S., January 12. Mr. N. Molyneux, Wickham.

ODONTIODA CHELSIENSIS.

This beautiful bigeneric hybrid, of which a characteristic illustration is given herewith, was raised in the nurseries of Messrs. William Bull and Sons, Chelsea, from a cross effected between Cochlioda vulcanica grandiflora and Odontoglossum crispum. The plant is of comparatively strong growth, and the flowers are of fine form, and deep rose-carmine richly shaded with violet-purple. The single flower in the illustration is reproduced in its natural size. This beautiful hybrid was exhibited by Messrs. W. Bull and Sons at the monthly meeting of the Manchester and North of England Orchid Society, held at Manchester on the 7th inst., and received the distinction of an Award of Merit.



ODONTIODA CHELSIENSIS.
Exhibited by Messrs. W. Bull and Sons at the meeting of the North of England Orchid Society, January 7, when it received an A.M. Colour, rose-carmine, shaded with violet-purple.

ODONTOGLOSSUM ARDENTISSIMUM NORMAN COOKSON.

A distinct and beautiful variety; the flowers of medium size, with broad, rounded sepals and petals, marked with very large blotches of red-purple on a white ground. A.M., R.H.S., January 12. Mr. Norman C. Cookson, Wylam-on-Tyne (gardener, Mr. H. J. Chapman).

CATTLEYA PERCIVALIANA, CHARLESWORTH'S VARIETY.

A remarkably handsome form, of which an illustration was given in our issue of the 16th inst. The flowers are comparatively large, the petals and sepals white, and the lip rich purple-crimson, marked with gold at the base. F.C.C., R.H.S., January 12. Messrs. Charlesworth and Co., Haywards Heath.

VANDA WATSONI.

A charming species, having a habit similar to that of V. Kimballiana, bearing erect spikes of small white flowers. A.M., R.H.S., January 12. Lieut.-Colonel Holford.

CATTLEYA MAGGIE RAPHAEL WESTONBIRT VARIETY.

A handsome form of this beautiful hybrid, which was obtained by the intercrossing of C. Dowiana aurea and C. Trianæ Imperator. The flowers are of large size and fine form; the petals are pale rose, and the lip rich purple-crimson, with golden reticulation at the base. A.M., R.H.S., January 12. Lieut.-Colonel Holford, Westonbirt (orchid grower, Mr. H. G. Alexander).

BEGONIA PATRIÆ.

A rather dwarf-growing begonia, obtained from a cross effected between B. socotrana and B. Pearcei. The plants are dense and free-branching, attain a height of ten or eleven inches, and produce a profusion of rather small, bright rose-pink flowers. The leaves are similar to the first-named of its parents, and the plants produce rudimentary tubers only, as in the case of other hybrids that have had as their parents B. socotrana and a tuberous-rooted variety. A.M., R.H.S., January 12. Messrs. Lemoine and Sons, Nancy, France.

PEAR BLICKLING.

A midwinter pear that has the recommendation of being a good cropper, of bearing fruit that is rich in flavour, and of ripening early in January, when first-class pears are none too plentiful. F.C.C., R.H.S., January 12. Colonel C. Harbord, Gunton Park, Norwich (gardener, Mr. W. Allan).

COLUMNEA MAGNIFICA.

An attractive gesnerad, discovered about the middle of the last century by Warscewicz in the province of Veraguas Panama, but it does not seem to have been collected again until 1906, when it was discovered in the mountains of Costa Rica by Carlos Wercklé at an altitude of between 6,000 and 7,000 feet. The plant attains a height of about twelve inches, has oblanceolate leaves, and large vermilion flowers, which are borne on the upper part of the stem. It thrives under the same conditions as gesnerias. Bot. Mag., t. 8225.

HIBISCUS APONEURUS.

A comparatively small-growing species, bearing bright scarlet flowers an inch or so in diameter, and thriving in a warm greenhouse. While not entitled to a foremost position among decorative plants, it is sufficiently attractive to justify it receiving the attention of cultivators, more especially as it is not difficult to grow. Bot. Mag., t. 8231.

EUPATORIUM RAFFILLI.

A valuable winter-flowering species closely allied to E. (Hebeclinium) ianthinum, under which name it has for some years been grown in the Birmingham Botanic Gardens. It is superior to that species, the flower heads being larger and of a richer purple hue, and the leaves are of finer proportions. Plants raised from cuttings early in the summer and grown on in a warm house attain to goodly proportions, and produce an effective display of bloom at midwinter, extending over four or five weeks. Bot. Mag., t. 8227.

SINGLE-FLOWERED CHRYSANTHEMUMS.

I was pleased to read what was so well said recently (p. 909, 1908, about single-flowered chrysanthemums, in the able leader on "The Past Chrysanthemum Season." For something over twenty years I have advocated the extension of this type for decorative purposes, both as plants and cut flowers, knowing well their value in decorations, and I am pleased to see that they now occupy so strong a position at the shows, interesting the public, and providing much pleasure at home.

The introduction, in 1885, of that charming variety Mary Anderson, by Teesdale, probably did more to hasten public interest in this type than any other one thing. The colour of this variety is so pleasing—blush white—as to enchant one at first sight; while its form leaves little to be desired. I am not acquainted with a single society which does not include a class or classes for this section in its schedule.

Nowhere in Great Britain can single varieties be seen in such fine condition as at the Edinburgh show, where they have vastly improved during the last few years. The Scottish Horticultural Association offers a first prize of £2 for six varieties, to be shown separately in 8-inch vases, and this produces a fine display of well-grown blooms. Just consider the effect made by as many as six dozen blooms of one variety in a vase, and so arranged that one flower does not interfere with its neighbour, and above a green base made by their own foliage. Given ample table space, and this sufficiently low to enable visitors to look down upon the blossoms, it is small wonder this type does receive favourable encomiums.

Contrast these conditions with the best encouragement offered by the leading English society—the National Chrysanthemum Society—which offers 30s. for "twelve vases, not less than six varieties"; as though there would be any difficulty in obtaining twelve distinct sorts! Although this class produced a strong entry, there was nothing particularly striking in any one of the exhibits. Much the best exhibit of these flowers at the November show was the premier prize entry of one vase, arranged with any foliage. There the true decorative effect of the flower was developed, and it received much notice and not a little admiration. In trade exhibits too single-flowered forms were more prominent than usual, showing that even the growers are recognising the trend of public opinion.

I would suggest that some of the varieties of the new race have too many florets, thus rendering them an approach to semi-doubles, which, in my opinion, is a step in the wrong direction. A single row of florets, or, at the most, two, is sufficient for a single-flowered variety.

E. Molyneux.

BRACKEN AS LITTER.

(Concluded from page 44.)

The Composition of the Dung.

The extent to which the litter contributes to the composition of dung depends very largely on the management. If the dung is made with large quantities of litter in open yards and exposed to rain so that the urine and soluble matters generally get washed away, a large proportion of its fertilising constituents comes from the litter. When dung is made in stalls with less litter and less liability to loss, the proportion of fertilising material contributed by the animals' excretions is greatly increased, and the litter plays a lesser part except as an absorbent. Dung made from bracken may for two reasons be expected to contain more nitrogen than straw-made dung; bracken contains more nitrogen than straw, and it has also a larger power of soaking up urine. The amount of potash present might be either higher or lower; bracken is poorer in potash than straw, but this deficiency is counteracted by its greater power of absorbing urine which contains the greater part of the potash voided by the animal, so that one would not expect much difference either way. These points are illustrated by the following analyses of dung made in the Haslemere district:

—	Water.	Nitrogen	Potash.	Phosphoric Acid.
Straw-made dung	69·2	0·67	0·91	0·32
Fern-made dung.	70·2	0·71	0·90	0·28

The fern dung is somewhat richer in nitrogen than the straw dung, and contains the same amount of potash. It was the lighter of the two, weighing less than an equal bulk of the straw dung. This may have been an accidental difference in making, but if it is generally true it indicates that bracken does not get trodden in so readily as straw, in which case it would not exert its full absorptive power, and would lose much of the advantage it possesses over straw. In spite of all this, however, the fern dung comes out slightly richer than the other.

The Rate of Decomposition of the Dung.

The rate at which dung will decay in the soil is a very important factor in cases like the present, where a comparison is being made between two lots of dung made from different littering materials. The coarse, fibrous matter of which the litter is composed has properties altogether different from those possessed by the black structureless humus into which it changes on decay. Fibrous material opens up a soil and prevents settling or panning down, it has no binding tendency on a light soil, but rather the reverse; it has no particular power of increasing the amount of water retained by the soil, on the contrary, by opening the soil and allowing air to enter and water vapour to escape it tends to bring about a loss of water. Humus, on the other hand, has a binding tendency, and causes a light soil to hold better together, it increases the water holding power of the soil, and keeps the soil moist. The properties of fibrous material may often make it very useful on a heavy soil where its power of lightening the soil and promoting aeration is an advantage, and its drying out tendency is no disadvantage because of the ample supply of water; but on a light, dry soil fibrous material may be harmful because it leads to loss of water, of which there is already a deficit. Dung in which the litter decomposes slowly will, therefore, be less useful on a light soil, but may be more useful on a heavy soil than dung in which the litter rots down quickly.

The respective behaviour of straw and fern dung was investigated by marking out two small plots and digging dung into them in November at the rate of 20 tons to the acre; one plot received the straw dung, the other the fern dung analysed above. At the end of March the ground was carefully forked over. The straw dung was found to have decomposed fairly completely into black humus, the fern dung had not, the leaves had decomposed, but the stems remained, and, indeed they seemed almost unaltered. It appears, then, that fern dung decomposes less rapidly in the soil and leaves behind it a larger residue of unchanged fibrous material than straw dung.

These observations enable us to explain a local preference that seems at first sight entirely a matter of prejudice. Gardeners on the light sands at Haslemere, where both straw and fern-made dung are available, prefer the straw dung and are willing to pay a higher price for it, alleging, among other reasons, that it is better and lasts longer in the soil. A little further off, however, on the heavy clay soils the fern dung is considered better. As is often the case with local preferences this is not entirely prejudice, but is capable of rational explanation. The fibrous residue remaining for some time after the application of the fern dung tends to open up the soil, to let in air and to let out water vapour on the light sand, already sufficiently aërated, but insufficiently supplied with water; this is a disadvantage, and goes to counteract the good effect of the rest of the manure, making it, on the whole, probably less useful than straw dung. On the heavier clay, the water supply is ample, but the air supply is not. In this case, therefore, the lightening and opening-up effect of the fern stems is an advantage.

Conclusion.

Where bracken can be obtained its use for litter is a matter deserving serious consideration. It suits the animals, though not so well as straw.

It contains three times as much nitrogen, and as much phosphoric acid as straw, but less potash. Its manurial value is about 50 per cent. higher than that of straw. It possesses greater power of absorbing ammonia and urine than an equal weight of straw, the fine leaves especially being effective. This increased power is, however, only shown to its full extent when the bracken is trodden in as completely as straw would have been.

Dung made from bracken may be expected to be somewhat richer than dung made from straw. On the other hand, it takes longer to decompose in the soil, the fibrous woody stems being only very slowly attacked. It therefore opens up the soil to a greater extent than straw-made dung would do, and is for that reason likely to be more effective on a heavy clay than on a light sandy soil.

Bulbs, Tubers, and Roots generally, whether of flowers or vegetables, which have been stored away for the winter, should be periodically examined, and in the event of any showing signs of decay, these should be promptly removed. Neglect in this respect means irreparable loss. If in the case of begonias, dahlias, etc., these should by some unforeseen cause become too damp, or be frozen owing to insufficient protection, decay will sooner or later set in. But by carefully examining the tubers during periods of inclement weather, very heavy losses, even in extreme instances, can be prevented. Shrivelling through over-dry conditions is equally fatal to roots and tubers, more so when these later have to be depended upon for propagating purposes. To prevent shrivelling, put a small quantity of lightly moistened cocoanut-fibre refuse among the roots. Potatoes which are held in store for seed purposes should have early attention, and, be the quantity large or small, they are best stored in wood trays specially constructed for this purpose; although for small quantities, garden seed or cutting boxes will answer the same purpose. Place the tubers on end with the most prominent eyes uppermost, and store in a cool shed which admits a fair amount of light, and is also absolutely frost-proof.—Thomas Smith.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

DECIDUOUS DENDROBIUMS.—Importations of such species as D. Wardianum, D. nobile, D. crassinode, D. Falconeri, D. devonianum, and others, are now, and will for some months to come, be frequently arriving, and the opportunities thus afforded of securing plants to replenish those kinds which usually deteriorate under cultivation should be taken advantage of. D. Wardianum is one of the most useful and beautiful, and in general gardens no orchid is more serviceable for decorative purposes, but where the leading growths have to be cut away for decorative purposes when in flower, there is but little left for the production of the future growth. Where plants have to be treated in this way I certainly would advise that the stock of this species should be annually replenished by securing imported plants. I would further suggest that the plants from the earlier importation should be secured. The summer seasons are usually of such short duration that the earlier the plants are started the better are the prospects of their maturing their growth under favourable conditions. Securing early imported plants is most essential when they are required to be in bloom earlier than the month of April.

STARTING IMPORTED DENDROBIUMS.—Where imported plants of the above-named dendrobiums are obtained shallow pans or baskets should be used. It is particularly desirable to avoid using a large quantity of potting material, and to use an ample drainage of clean crocks. Neat wire handles should be affixed, and where necessary the pseudo-bulbs should be secured to the wires or suitable stakes. The growths of such pendulous-growing kinds as D. Wardianum, D. Falconeri, and others should be permitted to extend naturally, and not be tied in an upright position until after the growth is completed. The general treatment of imported dendrobiums is not to afford too much root moisture until after the growths have become well advanced, or should they be placed in too warm conditions, a temperature of about 55 to 60 deg. is ample until after the new growths start. More liberal treatment may afterwards be given. Where the atmosphere of the house is on the dry side the pseudo-bulbs may be syringed overhead in bright weather just sufficient to keep them from shrivelling.

DENDROBIUM FORMOSUM. — The usefulness of this species appears to be generally overlooked in gardens. There is certainly no orchid flowering in the months of October and November that is more serviceable, either for decorations or the supply of cut flowers. Importations of this species usually reach this country during the spring months, and I consider that gardeners having the facilities of an ordinary plant stove should grow these plants in quantity. I am well aware that this species is considered somewhat difficult of cultivation, but it is grown more successfully now than in the past, and I am quite sure that, if the plants are grown suspended in an ordinary plant stove, with ample drainage and a small quantity of potting compost about the roots, the difficulties of culture will, to a great extent, be removed, and with this success assured D. formosum should become more generally appreciated.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

REPOTTING.—Even should the weather appear favourable for making a commencement, it will pay in the long run to wait a few weeks longer. We may yet have a return of the weather of December 29, when we registered 29 deg. of frost. Severe weather such as that would tend to check healthy development in the case of plants that have been disturbed at the roots. When plants commence to make fresh growth too soon in the new year, it is not a gain, for it involves a great cost in firing, and is injurious to plants, more especially is this so in the case of those which have had their roots pruned and partially shaken out of the old soil. It is better to wait until the sun's rays will give more warmth, and the conditions generally be much more favourable to healthy growth.

SPECIAL CASES.—Such plants as stephanotis, gardenias, and eucharis, required in bloom as early as possible, should be brought forward in a forcing pit by themselves, where the temperature can be maintained without much extra firing. If leaves and stable litter are used for plunging material, clear tepid water will be only necessary for producing the necessary moist condition of the atmosphere. If such materials as tan and cocoanut-fibre refuse are used, damp in the early part of the afternoon with liquid manure. Admit all the light possible by keeping the glass clean, to regulate the temperature and prevent the escape of moisture. When sharp frosts or cold searching winds prevail, regulate the temperature carefully; it is advisable to prevent a rapid fall of the temperature during darkness by having all accessible roofs covered with canvas upon wooden rollers, or upon wires with rings, which can be quickly applied.

GLOXINIAS.—Where successional batches of these lovely flowering plants are grown give frequent attention to see that they are not suffering from being kept too dry, or injured, as sometimes happens, by being in close contact with the hot-water pipes. A frequent mistake made with these bulbs is that of allowing them to start into growth unobserved. For the first batch the plants that show first signs of growth should be selected. They resent a close, heavy soil, and succeed best in a compost of fibrous loam, peat, and leaf-soil, mixed with a little sand. Make the compost moderately firm, and when the potting is completed the tops of the corms should be level with the surface. Place the plants on a bed of gravel or cocoanut-fibre refuse near to the glass in a structure in which a temperature of 60 deg. is maintained. It will be some time before the tubers make many roots, so that occasional damping the pots and surroundings with the syringe will be all that is really necessary.

GESNERA EXONIENSIS. — Plants that are now coming into flower may be assisted by occasional applications of weak liquid manure. Few stove subjects flowering in winter are more effective or more easily grown, the beautiful velvety leaves covered with shining red hairs, and the bold spikes of rich orange-red flowers combine to produce a rich effect. They remain in bloom a considerable time, a succession of flowers being produced in the course of the development of the spikes.—W. Fyfe, Lockinge Park Gardens.

HARDY FRUITS.

WALL TREES.—Any pruning and training remaining to be done should be attended to and finished as soon as possible. Loosen the trees from the walls, and brush over as much of the back portion of the main branches as it is possible to get at with soapy water or some approved insecticide, and give the walls a good syringing with paraffin emulsion to destroy as many as possible of the various pests which secrete themselves in the crevices. When securing the trees in their proper positions with ties or shreds, be careful to allow ample room between the branches, and thus prevent over-crowding of the foliage when the trees are in full growth. Young shoots should, if required, be reserved during the summer to take the place of unsatisfactory or worn-out branches. Those reserved for this purpose should be laid in the position they are required to fill, and if gross cut them back to about one-third of their length to ensure the growth of the back buds. Prune all laterals to within about an inch and a-half of their base, not just above the point of the summer pinching, which is sometimes done; also the leading branches of trees that have filled their allotted space. Young trees should have their leading growths pruned back about one-third of their length. Collect all prunings, shreds, and other tying material up, and have them burnt.

BUSH FRUITS.—Red and white currants, also gooseberries, require much the same treatment. Shorten the leading branches back to within six or eight inches of the old wood, and prune all laterals back to an inch. These are often left with their branches much too close together, with the result that the trees produce more fruit than can be brought to perfection. See that ample room is now provided by well thinning out the branches.

THE BLACK CURRANT differs from the red and white varieties in the manner of pruning, inasmuch as the fruit is chiefly produced on the young wood of the previous season. Therefore cut out as much of the old fruiting wood as can be spared to make room for the young shoots, and thin out the latter if necessary; also slightly shorten those left if very vigorous, to induce young growths to push from the lower parts of the bushes. Trees which have only a few enlarged buds on them should have all these carefully picked off and burnt, but where trees are found to be badly infested with the currant gall mite, they should be dug up and burnt. Dusting the bushes with a mixture of sulphur and lime during March, April, and May is recommended for its destruction.

WINTER SPRAYING. — After the trees are pruned they should be sprayed with the potash and soda emulsion, or by some other wash known to be efficient. Whatever kind of emulsion is used, spraying should be done as early after this date as possible.

FRUIT ROOM.—Examine the collections of fruit in hand frequently, removing any that show signs of decay. Late varieties, as Newton Wonder, Annie Elizabeth, Dumelow's Seedling, Claygate Pearmain, Reinette du Canada, and Sturmer Pippin among apples, and Bergamotte Esperen, Beurre Rance, Olivier de Serres, and Nec Plus Meuris among the pears, should have special attention and care to ensure their being sent to the table in good condition. Keep the room as cool as possible, and the atmosphere dry by admitting a little air through the ventilators on occasions when the temperature outside averages 40 deg. — George Woodgate, Rolleston Hall Gardens.

THE KITCHEN GARDEN.

THE FORCING of vegetables and salads will for the next few months claim a large share of attention to ensure the requisite quantities being prepared and planted to meet the demands. Where plenty of stable manure has been sweetened, and tree leaves preserved for this object, matters will be greatly facilitated. In all cases make the beds firm by constant treading as they are made, and incorporate plenty of leaves in them, thus prolonging the heat. The inside of the pits or frames that may be utilised for forcing should be white-washed or painted white, to obtain the maximum light to the crops. Potatoes that have been laid out singly to sprout should be planted before the shoots have attained any considerable length, provided the beds are in readiness to receive them by the temperature decreasing to a safe degree. Sowings of seeds of carrots, radishes, and turnips must also be made for succession as required. If a sowing of lettuce was made during the first days of this month, and placed in heat, the young plants will be nearly large enough for pricking out over a mild hot-bed at about six inches apart in fine, rich soil. They should be kept close till the young roots are pushing freely into the new soil, then more air may be gradually given as the weather will allow.

PEAS.—Make a sowing of peas in 60-sized pots or narrow boxes in a rather open porous compost, and place them on a covering of ashes in a cool frame. After the seed has germinated and the plants have appeared above the soil, give plenty of air on every favourable occasion, while during mild days the plants will be benefited by being fully exposed, thus ensuring sturdy growth. Early Giant, William the First, and Gradus are suitable and satisfactory for this sowing. Perhaps the last-named in the colder counties, as here, gives better returns as a second early. When the soil outside is in a sufficiently dry condition also make a sowing of one or more of the above varieties on a warm border in drills 6ft. apart; these will, in an average season, turn in for use at about six to nine days after the pot-sown ones. For narrow borders such varieties as Chelsea Gem, Excelsior, May Queen, or Mayflower are more suitable, and often give splendid results in these warm positions if mulched and watered when filling their pods.

BROAD BEANS. — A sowing should be made in a rather sheltered position in drills at about 2ft. apart, the beans being put 1ft. apart in the row. The variety that is sent out as Mammoth Longpod is very hardy and prolific for early crops. Early Longpod is also largely grown. Mice are sometimes troublesome with this crop, as with peas, and it is advisable, if pestered with them, to sow seed more thickly than is recommended, and afterwards thin out the plants to the desired distance.

RHUBARB.—Lift a quantity of crowns during fine weather, and expose them to the open for a few days, previous to placing them in the mushroom house for forcing, which will assist the earliest batch or two. As the season advances this will not be so necessary, as growth will more readily respond when placed in warmth.

SEAKALE.—A batch of crowns should be taken up from the open quarters and placed in trenches that they may be sheltered in case of severe frosts setting in and thereby be at hand for introducing to the forcing house as required.

GENERAL REMARKS.—Take every advantage to forward the wheeling on of manure and trenching the quarters. Too much importance cannot be attached to this part of kitchen gardening. Where it is possible map out the sites that different crops are to occupy, and treat them accordingly. For such seed beds as for carrots, onions, beet, etc., lay the land up to exposure by trenching early. Give a top-dressing of wood ashes or soot, and on heavy cropped land a dressing of lime is very beneficial. When the men are unable to work outside during bad weather, keep them occupied under cover in preparing the seakale throngs for planting later, examining the stock of roots, and removing any that may be decayed and are likely to contaminate others. —C. Flack, Cholmondeley Castle Gardens.

Shortia galacifolia is an exceedingly beautiful and interesting plant in the rock garden, growing in close tufts, and spreading by means of short underground stems. The leaves spring from a central crown, and are evergreen; their glossy surface is veined, and they assume a rich bronze-purple in autumn, which is retained throughout winter. The white-frilled pendulous flowers are produced late in March and April, on crimson-coloured stems, the bracts also being crimson. It grows six inches in height here, where planted in light sandy peat soil in a half-shady spot. Where the exposure is more open the growth is dwarfer and the leaves are correspondingly richer coloured. The history of Shortia galacifolia as recounted in "Flora and Sylva" is quite as interesting as the plant itself. "It was in the winter of 1788 that Michaux first found it in the mountains of Carolina. For years the imperfect specimen lay unnoticed till Asa Grey saw them in Michaux's Herbarium in Paris. Recognising in them an unknown species, a search for it began, which was only rewarded in the spring of 1877 with the finding of a tiny patch of plants upon the banks of the Catawba river in Dowell's County, North Carolina. This shortia has proved less rare than was at first supposed. It grows beneath trees in a light, moist soil of humus and leaf-mould, along with such plants as mitchella, asarum, and galax."—Flora Bot. 3, p. 8.—Thomas Smith, Walmsgate Gardens.

NOTES ON SOME NEW ROSES
No. III.

We now come to another selection of the new roses of 1908, and here the writer's comments must be taken for what they may be worth, since it has been his misfortune to have seen them at the exhibitions only; he has no knowledge of them as viewed growing.

Albatross, H.T. (W. Paul and Son).—Ivory-white, erect, globular, resembling White Lady, but possibly fuller. The growth is apparently moderate.

Buttercup Rambler (Paul and Son).—Deep golden-yellow in bud, paler in the more expanded flower. Bloom, single, and after the style of Reœ, small, and buttercup in form. A distinct colour.

Charlotte Klemm, H.T. (Turke).—Colour, brilliant fiery red. Flowers semi-double, of medium size, produced in clusters. Said to be a seedling of Fabvier, crossed with Alfred Colomb. In habit it resembles Fabvier, but more intense in colour. As exhibited by Messrs. William Paul and Son at the exhibition held in the R.H.S. Hall in July, it was most attractive.

Elaine, H.T. (William Paul and Son).—Colour pale lemon-white, buds tipped with pink, thick deep broad petals much reflexed. The raisers speak of it as having "a distinct cactus-like appearance."

Ecarlate, H.T. (Boytard).—Colour scarlet-red, cupped, half full medium-sized flowers, free, and very floriferous. Said to be mildew-proof, and for this reason it is likely to supersede Marquise de Salisbury, a variety it closely resembles. Has been finely staged in the decorative classes this year by Messrs. Frank Cant and Co. and other exhibitors. Probably an excellent variety.

Lady Godiva, Wichuraiana (Paul and Son). A soft flesh pink sport from Dorothy Perkins, very charming; well staged at the exhibitions this year, and finely illustrated in the GARDENERS' MAGAZINE; good.

Laurent Carle, H.T. (Pernet-Ducher). Colour brilliant carmine. Flowers, large, pointed, and fairly full. Vigorous and free.

Mrs. William Cooper, H.T. (Hugh Dickson). Colour deep rosy-pink. Flowers large, cupped, and of good substance; fragrant.

Paula, Tea (Paul and Son). Colour sulphur-yellow, semi-double, free, vigorous, and fragrant. Distinct.

Refulgence, Hybrid Sweet Briar (William Paul and Son). Remarkable for the size and brilliancy of its flowers, which are dazzling scarlet, semi-single, with rich golden stamens, produced in clusters, ten to twenty on a stem. It appears to be a great advance on the Penzance briars, and is most attractive and promising. Award of Merit, R.H.S.

Starlight, Multiflora (Paul and Son).—Colour, white suffused pink. Large single flowers. A notable addition to the multifloras.

Snowstorm, Hybrid Musk (Paul and Son). Colour, pure white. Flowers produced in clusters, semi-single, reminding one of R. alba. Very free flowering, and, what is most valuable, it is a perpetual, giving blooms well into the autumn. A vigorous bush. Promising.

White Dorothy, Wichuraiana (Benjamin Cant and Sons).—The best description of this beautiful rose is that it is a pure white Dorothy Perkins; if anything, stronger in growth, and flowers slightly larger than Dorothy Perkins, from which it is a sport. It was magnificently staged by the introducers at the N.R.S. exhibition at Manchester in six vases, having large trusses of clean, fresh flowers, contrasting well with the stout, deep green, glossy foliage. The flowers, it was stated, were all cut from maiden plants. Without any doubt it will soon be as popular, if not more so, as Dorothy Perkins. Gold Medal, N.R.S., Manchester.

Of the roses mentioned in the foregoing lists the writer's selection would be, first and foremost, W. R. Smith (Tea), together with Molly Sharman-Crawford (Tea), Dr. O. Donel Brown (Hybrid Tea), White Dorothy, Refulgence, and Snowstorm.

JOSEPH H. PEMBERTON.

INCURVED CHRYSANTHEMUMS.

In looking round the November show held at the Crystal Palace, I was struck by the indifferent quality of the blooms in the incurved section, and could not but deplore the lack of interest taken in this section, not only by visitors, but by cultivators. The Floral Committee of the National Chrysanthemum Society is much to blame for certificating varieties like Mrs. James Hygate, which is really a small Japanese variety, and was so classed the year previous. Such action on the part of an important and what should be a trustworthy body, cannot but lower the confidence of the public in its actions. Many of the varieties now admitted into the incurved section are, at the best, mongrels.

With a view of improving the colours of varieties in this section, raisers have fertilised the blooms with pollen of Japanese varieties, but, unfortunately, in the raising of new chrysanthemums no definite results can be depended upon. Good seedling varieties are quite a matter of chance, and no definite line of action in the selection of parents is of value. What was at one time a prolific source of new and improved varieties seems to be almost lost now. I allude to sporting, the origin and cause of which seems to be as far off as ever; experts cannot tell us anything fresh in this direction. Why we have fewer sports in any section of the chrysanthemum now than formerly is passing strange. Queen of England and its sports gave us as many as eight distinct varieties; Princess of Wales as many; Princess Teck half-a-dozen, and so on. Even in the Japanese section, which is much larger than any other, there is a great dearth of new and desirable additions as the result of sporting. Madame Paolo Radaelli is the most prolific variety that I can recall at the present moment, and even that, at the most, has given but three.

Varieties noted at the Crystal Palace as being most objectionable as incurved blooms, owing to their rough appearance and their lack of semblance to the true incurved or globe flower, were Mrs. A. H. Hall, H. Hearne, Mrs. James Hygate, W. Pascoe, Souvenir de W. Clibran, Triomphe de Montbrun, Lady Isabel, M. Muelenare, and Chrysanthemiste Bruant. As long as varieties like these are staged in the condition alluded to, there is little prospect of the section becoming more popular.

Much the best exhibit in the show in question was that in the class for twelve blooms, from Mr. J. Preece, Great Warley. The varieties included Clara Wells, which is a splendid addition from Australia, having all the characteristics of a true incurved bloom; and Daisy Southam, a desirable rich yellow with a deep bronze suffusion. Duchess of Fife, Embléme Poitevine, Godfrey's Eclipse, Buttercup, Mrs. G. Denyers, and Mrs. H. J. Jones were especially noteworthy for depth, solidity, and finish. Varieties like these cannot but be an improvement to any stand,

E. MOLYNEUX.

STATE AFFORESTATION.

The second report, relating to afforestation, of the Royal Commission on Coast Erosion, the Reclamation of Tidal Lands, and Afforestation, has been issued as a Blue Book (Cd. 4,460). The report is remarkable for its fulness and interest, and is especially deserving of the attention of those who are interested in the question of extending the area of woodlands and forests in this country. Attached to the report is the following summary of the conclusions at which the Commissioners have arrived.

Forestry as an Investment.

(1.) The natural conditions of soil and climate in the United Kingdom are favourable to the production of high-class commercial timber such as is annually imported into the country in very great quantities.

(2.) The afforestation of suitable lands in the United Kingdom, if undertaken on an adequate scale, and in accordance with well-recognised scientific principles, should prove at present prices a sound and remunerative investment.

(3.) In estimating the profits of sylviculture account must, moreover, be taken of two facts: the increasing consumption of timber per head of population all over the world, in spite of the introduction of alternative materials; and, further, the exploitation, waste, and destruction by fire of the virgin forests, especially those yielding the more important building timbers. Already a noticeable shortage of timber supply has resulted, as is evidenced by steadily rising prices and depreciating qualities in all markets. It seems impossible to escape from the conclusion that this tendency will be continued and accentuated, and that a steady and a very considerable rise in prices may be looked for throughout the present century. The security which afforestation offers for investment is therefore likely to be an improving one, with a corresponding increase in profits, but, to avoid all that is speculative, this prospect has been disregarded in framing our estimates.

Land Suitable for Sylviculture.

(4.) The amount of land suitable for afforestation, but not now under timber, in the United Kingdom may roughly be put at a maximum of 9,000,000 acres. In determining this figure two considerations have been taken into account, besides elevation and physical suitability of soil. The first is that the value of the land is not in excess of a sum on which a fair return may be anticipated on the expenditure. This will naturally vary according to the productive capacity of the soil and the crop which it will carry. The second consideration is that the land could not be more profitably utilised in any other way.

(5.) A forest of 9,000,000 acres, in which are represented the various series of age-classes, may be expected to yield 9,000,000 loads annually in perpetuity. The importation of foreign timber from temperate climates into the United Kingdom in the year 1907 exceeded 8,500,000 loads, or approximately the annual supply which could be expected from the afforestation of the above-mentioned area.

(6.) The withdrawal of 9,000,000 acres from its present uses would cause some gradual curtailment of food supplies and displacement of labour. Land suitable for afforestation is mostly devoted to the production of mutton. Calculations on the basis of the present consumption show that at most 60,000 tons, or 4.8 per cent. of the total home production of meat, or 2.6 per cent. of the present national consumption, would be ultimately displaced. As to labour, the employment furnished by the present uses, mostly sheep farming, to which the land in question is devoted, may be taken to average one man to 1,000 acres. This does not represent one-tenth of the permanent employment afforded by the maintenance of a similar area of land under forest.

(7.) Systematic sylviculture aims at the production of a steady and continuous supply of marketable timber. To ensure the maintenance of these supplies the area should be divided for planting by the average number of years which the crop needs to mature; for example, if the life of the crop be taken as eighty years, the area to be afforested every year would, out of a total area of 9,000,000 acres, be 112,500 acres. But a more rapid system of planting may be adopted without seriously complicating the rotation, and, further, some adaptation to the temporary fluctuations of the labour market is feasible.

(8.) The distribution of this 9,000,000 acres of suitable land is somewhat irregular. By far the largest areas are to be met with in the west and north of England, and throughout similar regions in Scotland, Ireland, and Wales also contain a relatively large amount of this type of land. In the south and east of England, on the other hand, the areas in the aggregate are less extensive. Great diversity exists in the size of these areas, some counties offering large contiguous stretches, while in others the areas are characterised by their discontinuous nature.

Administration of Woods and Forests.

(9.) The administration of national forest lands should be entrusted to special Commissioners.

(10.) In dealing with these lands, sub-division into distinct districts, with an executive and administrative sub-centre, commends itself from various points of view. Thus local employment would be afforded, local subsidiary industries would be encouraged, public recreation grounds would be provided, and, in connection with the establishment of such forests, small holdings would undoubtedly be multiplied.

(11.) Sylviculture in the United Kingdom is an enterprise which rarely appeals to the private landowner or capitalist. The prolonged time for which capital must be locked up before any return can be expected, the loss of rent and burden of rates over the whole period, and the absence of security for continuous care and management, act as deterrents. None of these objections applies to the State, whose corporate life and resources lend themselves in an especial degree to an undertaking of this character. If the State plants, it will certainly reap, which the individual owner can rarely hope to do.

(12.) If afforestation be promoted on a large scale the provision of suitable lands is the first step. For this purpose a general survey should be made, and the extent and distribution of such lands ascertained. As a rule, it will be found expedient for the State to purchase from time to time such areas as are destined for planting, but some progress may conceivably be made along the lines of profit-sharing, in which case the owner would forego the purchase price. Experience proves that, although much of the land required may be expected to be purchasable by voluntary treaty, yet compulsory powers would be necessary to facilitate transactions where voluntary treaty had broken down.

A Comprehensive Scheme.

(13.) The value of land falling within the definition of "suitability" may be taken, except in rare instances, to lie between £2 and £10 freehold value; but the average value of suitable lands, including the necessary buildings, and other preliminary equipment, may be taken as £6 10s. per acre, and the average cost of afforestation also at £6 10s. per acre. If 150,000 acres be annually taken in hand, a sum of about £2,000,000 would be needed annually to finance the undertaking.

(14.) Money expended in afforestation differs in kind from other calls on the national purse. It is a productive investment of capital. To provide this capital sum out of taxes would be an act of unprecedented generosity on the part of the present generation of taxpayers in favour of their posterity. No stronger justification for proceeding by loan than a reproductive outlay exists. The loan should be based on actuarial calculations showing initial cost, expenses of upkeep and management calculated at compound interest over the whole period, and the value of the property when fully matured. Such actuarial statements we have given, which show for the full scheme that, after allowing 3 per cent. compound interest on all the capital invested, the approximate equalised revenue would at the end of eighty years amount to £17,411,000 per annum, while the value of the property might be expected to be £562,075,000, or £106,993,000 in excess of the sum involved in its creation. A smaller scheme involving the afforestation of 6,000,000 acres (75,000 acres annually for eighty years) would show a profit of about £10,000,000 annually, or a capital value of £320,000,000, being £60,944,000 in excess of the cost of production.

(15.) Coming to ways and means by which a loan of this character may best be provided, a point of great importance to be borne in mind is that, although the period of rotation of a timber crop may be taken as eighty years, yet after forty years, owing to the value of thinnings, and the receipts of some short-period crops, the forest becomes practically self-supporting. Between the fortieth and eightieth years, the sales of timber will be sufficient to meet the annual charges, including the upkeep and the extension of the forest. After the eightieth year a large annual revenue will be derived. These considerations point to a free loan from the Treasury to the Forest Commissioners; the net deficit to be met would in the first year be £90,000 or £45,000, according to the extent of the operation, and would reach its maximum in the fortieth year, amounting in that year to £3,131,250 or £1,565,625. After this period the deficit would be insignificant, while in the eighty-first year the revenue derived would be £17,411,000 or £10,000,000 respectively, representing about 3¾ per cent. on the total accumulated costs of the undertaking.

Increase of Employment.

(16.) On the question of labour and its relations to forestry, the conclusions to which the evidence before them leads your Commissioners are, that the operations involved in afforestation vary in the degree of requisite skill from little or none in rough road-making and surface draining to a considerable amount in the planting. Your Commissioners wish to make it clear that they have in contemplation a scheme of national afforestation on economic lines. They have no hesitation in asserting that there are in the United Kingdom at any time, and especially in winter, thousands of men out of work for longer or shorter periods, who are quite ready and able to perform the less skilled work without previous training, and with satisfactory results. There is a still larger class of unemployed who are capable of being trained to perform this or the higher class of labour, and such men can, if desired, be recruited through labour colonies, distress committees, labour bureaux, or charitable agencies. There is, then, no need to accept inefficient labour with the object of affording occupation to the unemployed. The labour employed in the national forests should not fall below the ordinary standards, and should be remunerated at the ordinary rate of the district for similar labour. Subject to the requisite standard of efficiency being attained, preference should be given to those temporarily or permanently unemployed in the district, especially where evidence of such efficiency can be furnished by public or private agencies for the reclamation and training of the unemployed class.

(17.) To establish afforestation on commercial lines does not, however, preclude its being used as an instrument of social regeneration. A broad view of economics cannot exclude from its cognisance the grave national charge which unemployment with all its concomitant results involves, to say nothing of the personal deterioration by which it is often accompanied. Sylviculture is not unsuitable for building up the moral and physical fibre of even the most depressed of the unemployed classes, and its agency may well be invoked for this purpose, and advantage taken of its healthy and wholesome influences, provided that any additional expense incurred by the employment of less efficient labour be defrayed from a separate account.

Amount of Employment.

(18.) In estimating the amount of employment furnished by afforestation it is well to distinguish between the temporary labour involved in the creation of the forest and the permanent labour needed for its maintenance. Taking varying circumstances into consideration, it may be said that, on the average, it will take twelve men to afforest 100 acres in the planting season of four to five months, and that every 100 acres afforested will provide permanent employment for at least one man. If 150,000 acres be anually taken in hand, the labour of 18,000 men will be needed and permanent employment will in due course be afforded to 1,500 men, rising by an additional 1,500 every year until the end of the rotation. The number permanently employed would then approach 100,000. The labour absorbed by felling and converting timber, to say nothing of subsidiary industries which spring up around a timber supply, has been considered too remote to warrant detailed estimation, but there is undoubtedly a large field of employment in this connection. It is important to remember that, on the basis of £1,000,000 being annually spent on the operations of afforestation, apart from the cost of the land, employment would be afforded, directly and indirectly, to many more than 18,000 men. Indeed, the number employed may be roughly taken to be represented by about double that figure. For the incidental occupations, such as building, the making of implements, the provision of materials, etc., all involve the employment of additional labour.

(19.) A special advantage of forestry in relation to labour is that it offers a new source of employment. The labour connected with timber and timber products imported into the country is performed abroad, and thousands of families are maintained on the produce of the labour associated with the timber industry. Another advantage bound up with the extension of sylviculture is that the market for its produce is so great that it is inconceivable that it could seriously interfere with the output from private woodlands, and no difficulty of competition between the State and individuals need be apprehended.

(20.) The acquisition of grazing areas, private or common, for sylviculture might necessitate a modification of the existing agricultural system on certain farms. It is unreasonable to suppose that the remaining lowland areas on such farms could not, in many cases, either be adapted to other forms of agriculture or be profitably utilised for small holdings. Further, the conversion of comparatively unprofitable lands into forests enhances the productiveness of the adjacent areas, and should materially assist the small holdings movement. It has also the advantage of furnishing winter employment to small holders.

FORTHCOMING ENGAGEMENTS.

SATURDAY, January 23.—Annual dinner of the French Horticultural Society of London, at the Café Royal, at 6.30 p.m.; Sir Albert K. Rollit will preside.

TUESDAY, January 26.—Royal Horticultural Society: Fruit, Floral, and Orchid Committees meet at noon; general meeting and lecture on "A Method of using Domestic Sewage in Horticulture," by Mr. W. D. Scott Moncreiff, at 3 o'clock; Scientific Committee at 4 o'clock.

WEDNESDAY, January 27.—Royal Society of Arts meeting.

DESTRUCTION OF VERMIN. — Most [illegible] are pestered with Rats and Mice. Every effort should be made at this time of the year to exterminate them before seeds are sown. Danysz Virus is [illegible] stuff for killing these vermin. Single tube, 2s.; three tubes, 5s. Post free from DANYSZ VIRUS LTD., 52 Leadenhall Street, Garden Dept., London, E.C.—[Advt.]

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

SCIENTIFIC COMMITTEE, JANUARY 12.

Present: Mr. E. A. Bowles, M.A., F.L.S. (in the chair), Dr. M. C. Cooke, Messrs. Hales, Chapman, Güssow, Fawcett, Worsdell, Saunders, Fraser, Holmes, Bennett-Pöe, Rolfe, and Chittenden (secretary).

RICHARDIA DISEASED.—A large spathe of R. æthiopica was exhibited having about half the outer part brown and dead. Similar brown spots had appeared upon the leaves. No fungus was present, and the committee thought that in all probability the trouble was due to overfeeding.

MALFORMED ORCHID. — From Mr. Lynch, V.M.H., of Cambridge Botanic Garden, came a malformed flower of Cypripedium Dominianum with a normal flower for comparison. The flower had the sepals fused and a double lip; it was taken by Mr. Saunders for further examination.

DISEASED CARNATIONS.—Specimens of diseased carnations from Natal, where a very large number of plants had suffered at all stages. These were referred to Mr. Saunders and other members of the committee for further investigation.

NOMENCLATURE OF MULTIGENERIC ORCHID HYBRIDS. — The chairman announced that the sub-committee appointed to consider this question had arrived at the decision that the best solution of the question lay in coining names for each of the combinations of genera made, consisting of a commemorative name and the termination "ara." The full text of their finding will be laid before the committee at an early date.

PARASITIC ROSE CANKER.—Mr. Chittenden showed specimens of the rose canker described in the Journal R.H.S., vol. xxxiv., p. 222. The roses attacked had been imported from Germany three years since.

Birmingham Gardeners' Association.

The presentation of the annual report, balance-sheet, and election of officers and committee for 1909 took place on January 11. The principal event in connection with the election of officers was the resignation of the respected chairman, Mr. Walter Jones, who succeeded Mr. W. B. Latham in that office in 1905. Mr. Jones was actuated in resigning chiefly owing to the inconvenience occasioned by his recent change of residence, and the distance from the meetings. As an expression of the high esteem in which Mr. Jones was held by the members he was elected a vice-president of the society, and in responding he said he would attend the general meetings as often as possible, and continue to promote the interests and welfare of the society to the best of his ability.

In proposing a successor to the vacant chair Mr. Jones heartily advocated the election of the vice-chairman, Mr. T. Humphreys (curator, The Botanical Gardens, Edgbaston, Birmingham), and this was unanimously endorsed. Mr. C. H. Herbert (one of the oldest members of the society) was elected vice-chairman. Mr. William Spinks was re-elected treasurer; Mr. William Gardiner, librarian; and Mr. W. L. Deedman, secretary. The remaining members of the committee were re-elected, with the exception of Messrs. William Morter, T. Mumford, and E. Burden, who were succeeded by Messrs. George Giles, James Webb, and A. D. Christie.

The appointment of a new president, made necessary by the resignation of Mr. Walter E. Collinge, M.S.C., F.E.S. (late of the Birmingham University), was postponed for the time being.

East Anglian Horticultural Club.

The nineteenth annual dinner was held on the 13th inst. at the Boar's Head Hotel, Norwich. The tables were prettily decorated with pot plants from Messrs. Daniels Bros., Lim., nurseries, and cut flowers from the members. Mr. J. Powley was in the chair, supported by Messrs. T. B. Field, J. E. T. Pollard, W. Smith, Charles Daniels, W. Chettleburgh, L. Smith, P. G. Bishop, H. Goude, J. Clayton, James Forder, H. Perry, J. F. Betts, Mr. W. L. Wallis (the popular secretary), and many other of the leading local horticulturists.

After the loyal toasts had been duly honoured Mr. J. E. T. Pollard submitted that of "Success to the East Anglian Horticultural Club." He was pleased to note that such a splendid report could be issued—a membership of 346, and funds in hand £139 16s. 6d. The president suitably responded. Mr. L. Smith proposed "Success to the Norfolk and Norwich Horticultural Society." He said he was sorry that this society, which had been holding flower shows in and around Norwich for over 70 years, seemed to be losing public favour. It was not due to the exhibits or exhibitors, they were as keen as ever. It was public apathy. Still, he looked ahead for better times. Mr. William Smith replied, and said that 1908 was not such a bad year for them as 1907. He had, of course, received much advice on how to make the finances increase, but his general answer was, let us have more subscribing members.

Mr. T. B. Field gave the toast of "The Royal Horticultural Society," and in the course of some excellent remarks, said how much to the advantage of the young members it would be if they entered the examinations of the R.H.S., and were able to secure a certificate of proficiency. Mr. Charles Daniels responded, and gave some facts and figures of the useful work being carried on by the society at Wisley. He introduced a local suggestion worthy of further consideration, viz., that of establishing a small experimental garden in the city or suburbs for botanical and horticultural instruction. Several other toasts were given, and some capital songs rendered.

Reading Gardeners' Association.

The annual general meeting of this flourishing society was held in the Abbey Hall, Reading (by kind permission of Messrs. Sutton and Sons), and there was a very large assemblage of members. The number from a distance who attended being particularly noticeable, Maidenhead, Henley, Wokingham, Pangbourne, etc., being strongly represented.

The principal business of the meeting was the election of officers for the ensuing year, and the passing of the balance-sheet and committee's report for 1908. Mr. Alderman Parfitt, J.P. (president), occupied the chair.

The minutes of the last annual meeting having been confirmed and signed, the Secretary read the report of the association's doings during the year which has just closed, fully reviewing the work, also the pleasures of the society, special reference being made to the excursions to Guildford, Aldenham House Gardens, and to the president's fruit plantation at Caversham.

The balance-sheet was then presented by the Hon. Treasurer, and showed the association to be in a highly satisfactory condition financially.

The election of officers then took place, and resulted as follows: President, Mr. Alderman F. B. Parfitt, J.P.; vice-president, Mr. Leonard Sutton, J.P.; trustees, Mr. A. C. Bartholomew and Mr. Martin J. Sutton, J.P.; chairman, Mr. A. F. Bailey; vice-chairman, Mr. H. C. Loader; librarian, Mr. E. J. Dore, assistant librarian, Mr. F. W. Exler; treasurer, Mr. F. W. Macdonald, F.R.H.S.; auditors, Messrs. W. Badcock and A. Smith; hon. secretary, Mr. L. Castle; committee, Messrs. F. Alexander, F. Barnes, W. Blackwell, W. C. Blaxill, H. G. Cox, D. Dore, C. Foster, F.R.H.S., R. A. Hatton, G. Herridge, G. Hinton, T. Judd, T. Neve, T. J. Powell, G. Stanton, F.R.H.S., F. Townsend, W. J. Townsend, T. Tunbridge, P.C., F.R.H.S., W. Turnham, W. H. Wilson, and J. Wynn.

Votes of thanks were accorded the retiring chairman, Mr. T. Tunbridge; and vice-chairman, Mr. G. Hinton. On the proposition of the Vice-President, it was resolved that the annual tea and entertainment take place as usual, arrangements being left in the hands of a sub-committee. Mr. Chas. Foster, F.R.H.S., Assistant Director in Horticulture at the University College, Reading, kindly exhibited some beautifully-grown specimens of Sutton's Eclipse and Sutton's Sunbeam tomatoes, the fruit being intended for transit to London was displayed in boxes to illustrate the correct method of packing for despatch by rail.

A hearty vote of thanks to the president concluded the meeting. Several new members were elected.

Chester Paxton Society.

Mr. J. D. Siddall spoke on "Winter Botany" at the meeting of the Chester Paxton Society, held on Saturday at the Grosvenor Museum. The lecture was illustrated by a set of beautiful lantern slides.

Mr. A. W. Armstrong presided, and briefly introduced Mr. Siddall, who dealt with the aspects of plant life in winter, including British plants which are to be found in flower during the winter months. Particulars of several of the winter-flowering shrubs and berry-bearing plants were also given, these being illustrated by actual specimens, including some beautiful sprays of the Arbutus unedo (Strawberry Tree). Indoor flowering plants were also dealt with, this part of the subject being illustrated by some fine examples of Japanese chrysanthemums, as well as several reproductions of photographs taken at the society's exhibitions at the Town Hall. At the close of the lecture, Mr. Siddall was, on the proposition of Mr. J. Naylor, seconded by Mr. R. Wakefield, accorded a hearty vote of thanks.

Sweet Peas

When growing Sweet Peas, grow only the best. The best that can be obtained are Eckford's.

1909 COLLECTIONS.

Villa (B) Collection.
24 splendid varieties, separate and named, suitable for exhibition, 50 seeds of each, **5/6.**

Villa (C) Collection.
12 splendid varieties, separate and named, suitable for exhibition, 50 seeds of each, **2/9.**

Villa (E) Collection.
12 splendid varieties, separate and named, suitable for exhibition, 25 seeds of each. **1/6.**

A Booklet giving full particulars on the Culture of Sweet Peas, given with every order.

Eckford's Culinary Peas also lead, a trial 4 pints for complete succession, **3 6**, post free.

FREE. Send a post-card for Coloured Illustrated and Full Descriptive Catalogue. It is sent post free. Write to-day.

SHROPSHIRE

Bath Gardeners' Debating Society.

The first meeting of the new session of this society was held at the Foresters' Hall, on Monday, Mr. T. Parrott presiding over a large attendance of members. The paper for the evening was read by Mr. A. Bailey, on "Achimenes." He said he did not know for what reason these flowers were less popular than they were some twenty or thirty years ago, when they were very great favourites. As summer flowers they had been somewhat displaced by the enormous strides made by their rivals the begonia and gloxinia. He, however, thought the time was not far distant when they would again attain to a high degree of popularity. Well-grown specimens made excellent subjects for the conservatory and house decoration. They were to be had in various colours, and no doubt if a greater demand arose others would follow. The lecturer then touched on their introduction and cultural treatment. The discussion following was taken part in by several of the members. A hearty vote of thanks was accorded Mr. Bailey for his paper. Four new members were elected.

Esher.

On Wednesday, the 13th inst., Mr. Edwin Beckett, V.M.H., of Aldenham House Gardens, Elstree, had the honour of giving a lecture before Her Royal Highness the Duchess of Albany, who was attended by Captain Seymour and Mrs. Royle, and a large audience, including the principal residents of Esher, at the Parish Hall. Mr. S. A. P. Kitcat, the newly-elected president, received the Royal party, and introduced the lecturer.

Mr. Beckett took for the subject of his lecture, "Vegetables and Their Culture," and made reference to all the more important points connected with this branch of gardening. The lecture was illustrated by a large number of lantern slides, these showing the best types of vegetables to grow; also many of the collections which he has exhibited at various times at the leading shows in the United Kingdom. The lecturer also made mention of the rapid strides which have been made during recent years in encouraging the cultivation of vegetables.

Mr. Beckett was asked many questions at the close of his lecture, and was accorded a hearty vote of thanks for his instructive and interesting address.

ANSWERS TO CORRESPONDENTS.

LIME-WASH ON HOT-WATER PIPES.—C. J., Brentford: The use of lime-wash on the hot-water pipes is not at all likely to prove harmful to the vines, or to pot plants, as the application would, we assume, be made when the vines are dormant. Lime would tend to injure the pipes in a very small way, and its use as a coating is very objectionable, the repeated coatings tending to keep the heat in instead of allowing it to radiate. There are some special mixtures for painting hot-water pipes with, but you may safely rely upon the old-fashioned method of using lamp-black and oil. Have the pipes thoroughly cleaned before applying the lamp-black.

KALANCHOE FLAMMEA.—E. C., Kenilworth: Put briefly, the cultivation of Kalanchoe flammea consists in sowing the seeds in well-drained pans of sandy soil during March or April, in a temperature of 60 to 70 deg., and the seeds need very little soil over them. Very little water will be needed by the seedlings, and they must be kept near the glass and soon transferred to a temperature of 55 to 65 deg., and this temperature, allowing for a rise by sunheat, should be provided all through the summer and autumn. No fire heat will be necessary for several months, but at all times it must be remembered that kalanchoes love light and sunshine, and do not like excess of moisture, either at the roots or in the atmosphere. Overpotting must be avoided; 48 and 32-sized pots are ample for good specimens. Sandy loam, some old dried cow manure, crushed mortar rubbish, and sand make up a suitable compost. In the case of old plants hardly any water will be needed from November to March, a moderate amount from August to November, and larger supplies from April to August; this, of course, is only a general rule. Propagation can be readily effected by means of cuttings of young shoots about three inches long, inserted in sandy soil about June or July, and placed on a shelf in a greenhouse. The cuttings should be left exposed to the light for two or three days before being inserted. Cut down the old plants directly they have finished flowering, and repot again in spring when new growth commences.

DAMAGED HYACINTHS.—R. B., Worsley: The hyacinths should have been removed from the plunging material before the leaves began to open, and while yet the growth was practically solid. After the leaves opened the moist plunging material came into contact with the delicate bloom spike, and, besides surrounding it with unsuitable conditions of moisture, kept it dark and pressed down upon it. The result is that decay followed injury, and some of the best bulbs are now useless, so far as flowering this season is concerned, and in all probability they are so much injured as to be absolutely useless.

IN THE
Gardeners' Magazine,
FEBRUARY 6th and 13th.
Price TWOPENCE each number; by post, 2½d.
Offices: 148 and 149, Aldersgate Street, London

CALADIUMS.—A. R. C., Winchester: Unless you have a special end in view, February will be quite soon enough to start the caladiums, placing the corms in pots just large enough to accommodate them, and potting them into larger sizes as roots and growths advance.

CALLISTEPHUS. — E. F., Oxford: The Callistephus is the China Aster, but we have become so used to regarding the numerous beautiful garden varieties of this annual as asters, and they are so catalogued in seed lists, that those not in touch with botanical nomenclature are not seldom led to believe that Aster is the generic title. Callistephus hortensis, or Chinensis is the botanical name of the China Aster, while the Asters, botanically considered, are the plants we know popularly as Michaelmas Daisies.

MOSSY LAWN.—I. M. P., Worcester: The fact that the lawn is poor and mossy at once proves that the soil and position are by no means good. A large amount of moss in a lawn usually indicates lack of proper drainage, therefore, your first business must be to consider whether it is desirable or necessary to cut drains across the lawn. If draining cannot be performed, the next best thing is to work over the lawn vigorously with a sharp toothed iron rake, working out the moss by this means. Such work makes the lawn look very bad for a short time, but the removal of the moss, and the scarifying given by the rake, both assist the grass considerably, giving it a chance to tiller-out and spread. Having thoroughly worked the lawn in this fashion, and carted away and burned the moss, leave all alone for a week or ten days. Meanwhile prepare a quantity of fine rich soil, such as old potting soil, hot-bed material, ashes from burnt garden refuse, road sweepings, etc., passing it all through a fine-meshed sieve and thoroughly mixing it. Add to this compost about one-sixth of its bulk of fresh air-slaked lime, and then apply as soon as possible, at the rate of 200 bushels per half-acre. Spread the material evenly, and rake it in carefully. It may be a good plan to sow grass seeds towards the end of March, and if you tell your seedsman the kind of soil and position you have to deal with he will supply suitable renovating mixture.

MISTLETOE.—F. B., Woodford Green. March is usually regarded as the best time for the insertion of mistletoe seeds into the crevice of the bark of a suitable tree, such as the apple, lime, poplar, oak, thorn, maple, or Mountain Ash. A notch should be made in the bark, if one does not already exist, on the underside of the selected branch, and into this the ripe berry and seeds should be pressed. A thin piece of muslin may be tied round the branch so as to cover the inserted berry, and thus prevent birds from extracting it. The covering must be examined from time to time, and be removed directly germination has commenced.

NAMES OF PLANTS.

W. P., West Norwood.—Viburnum odoratissimum.

C. V. B., Rotherham.—A seedling form of Begonia Rex.

C. S., Dorking.—1, Yucca aloeifolia; 2, Picea Pinsapo; 3, Arbutus unedo.

M. B. J., Chester.—1, Pandanus utilis; 2, Sonerilla marmorata; 3, Begonia fuchsioides; 4, Exacum affine.

F. P., Canterbury.—1, a Bauhinia, probably B. racemosa; 2, Citrus japonica; 3, Lachenalia Nelsoni.

L. C. D., Bideford.—1, Odontoglossum crispum, a pretty variety, but not a specially valuable one; 2, Maxillaria luteo-alba; 3, Cypripedium Leeanum.

NAMES OF FRUITS.

F. R., Rochester.—Bergamotte Esperen.

B. M. S., Sutton.—1, Court of Wick; 2, Waltham Abbey Seedling; 3, not recognised.

A. H. T., Leicester.—1, Yorkshire Greening; 2, probably Pearson's Plate; 3, Nonpareil.

M. T. J., Colchester.—1, Hambledon Deux Ans; 2, Beauty of Kent; 3, Court Pendu Plat; 4, Norfolk Beefing.

THE GARDEN BEAUTIFUL

"HAWL-MARK" SEEDS.

To protect the public against spurious substitution of inferior goods we have registered the word "Hawlmark," which stands for all that is best in the horticultural world.

The "Hawlmark" Collections of Sweet Peas for 1909 even surpass in value those of past years, which have earned for Alex. Dickson and Sons such a high reputation.

Write for Illustrated Seed List, which alone contains full trial ground reports, and in the pages of which will be found offers which no [illegible] of the Garden Beautiful should fail to consult.

V1 FLUID
THE WINTER SPRAY FLUID.

THE PRIORY GARDENS, ROEHAMPTON, S.W. November 14th, 1908.

Sirs,—I purchased 2 gallons of V1 and sprayed about half the trees under my charge here, doing the other half with another preparation. I have much pleasure in saying that V1 has exceeded my expectations; the trees kept clean all the Summer, with the exception of a slight attack of Green Fly upon the young shoots of some plum trees, which was soon got rid of by an application of V2 Fluid. I have no hesitation in saying that if your two Fluids are as effectual in the future as they have been here this season, no one need have dirty trees or maggoty and misshapen fruits.

Yours respectfully, **D. CAMPBELL.**

V1 FLUID IS EASY TO MIX AND EASY TO APPLY.
1 Gallon of Fluid makes 100 Gallons of Spray Mixture.

CATALOGUES RECEIVED.

ROBERT SYDENHAM, LIM., 33, TENBY STREET, BIRMINGHAM.—Unique list of the best vegetable and flower seeds. An admirably prepared and well-illustrated catalogue of moderate proportions, and therefore most convenient for shelf or pocket. Although of medium size, the catalogue contains the finest of the varieties of the several kinds of vegetables, and the best of the ornamental plants that are usually grown from seeds. The descriptions are concise throughout, but so clear as to afford much assistance in making selections. A finely executed plate in colours of some of the recently introduced sweet peas is issued with the catalogue.

MESSRS. J. CARTER AND CO., HIGH HOLBORN, LONDON.—Lawns and gardens.—This is a comprehensive catalogue of vegetable and flower seeds, and the full lists and the numerous illustrations form a substantial, handy, and useful volume.

No Garden can be Productive if Pests of the Soil Prey upon the Plants.

The growth of the garden is checked and retarded, and its life weakened, by the myriad insect pests of the soil that fatten upon plants and flowers.

Prompt treatment of the soil with the only absolutely effective pest-killer yet produced—

Kilogrub

Is the only way to remedy this evil.

Work "KILOGRUB" well into the soil, using only 2 or 3 ounces to a square yard—and let it do the rest.

It throws off poisonous fumes which are fatal to insect life, but cannot harm plants or animals.

"KILOGRUB" has been thoroughly tested, and hundreds of gardeners are glad they've tried it.

Prices, cash with order, carriage paid:—

7 lbs.	**2s. 0d.**
¼ cwt.	**5s. 0d.**
½ cwt.	**7s. 0d.**

SOW NOW UNDER GLASS.

SUTTON'S SUPERLATIVE MELON.
Per packet, 2s. 6d., post free.
Mr. A. Gaedecke, gardener to J. Ferguson Pullar, Esq., writes: "I had a grand crop of Sutton's Superlative Melon. I think this is the best Scarlet Melon in existence; it sets freely, even in a frame. I won First Prize at Perth against a very strong competition."

SUTTON AND SONS, THE KING'S SEEDSMEN, READING.

NOW IS THE TIME TO PLANT (the best time of the whole year)
KELWAY'S BEAUTIFUL BLUE DELPHINIUMS.
Hardy, and flourishing in every garden, they are the STATELIEST of PERENNIAL PLANTS for borders or beds; these celebrated improvements are invaluable for their introduction of that precious colour—blue—in masses to the garden. KELWAY and SON developed this race, and they should be procured direct from the Royal Horticulturists, Langport.

KELWAY'S IMPROVED DELPHINIUMS are now ready, strong plants, in choice named selections. Collection "B," 15s. per doz. Collection "D," 42s. per doz. Delivery free for remittance with order. KELWAY and SON, The Royal Horticulturists, Langport, Somerset.

FRANCO-BRITISH EXHIBITION, 1908. ONE of the ONLY THREE Gold Medals (or Higher Awards) (open to the whole world for permanent exhibits) awarded by the International Jury, and confirmed by the Governing Council was awarded to Kelway and Son; vide the AUTHORISED LIST published in the Press.—KELWAY and SON, Langport, Somerset.

FOR PRESENT PLANTING.

PLANTERS of FRUIT TREES should write for our fully descriptive catalogue and supplement, 6d., post free; and gratis to customers.

Well-ripened trees of all kinds, and our large, developed specimens of Vines, Figs, Peaches, and Nectarines, are especially good.

An inspection solicited.

GEORGE BUNYARD AND CO., Ltd.
The Royal Nurseries, MAIDSTONE.

CANNELLS' SWEET PEAS. — Suttons' Queen, Lord Nelson, Nora Unwin, Primrose Spencer, George Herbert, Frank Dolby. 15 Seeds each. Collection 1s., post free. CANNELLS, Loddon, Norfolk.

CAULIFLOWER, CANNELLS' EARLIEST OF ALL.—The earliest Cauliflower grown in our trials was a fortnight ahead of any other variety. Sow now. Packets, 1s., 1s. 6d., 2s. 6d. CANNELLS Loddon, Norfolk.

£100 FOR A SINGLE ONION was the prize we awarded in our recent Leamington Giant Onion Competition. We are offering £200 in Prizes this year. Particulars in all 1s. and 2s. 6d. packets of Leamington Giant Onion Seed.
ROGERS, LTD., Seedsmen, Leamington.

TO-DAY! AND FOR YEARS AND YEARS PAST the XL ALL Specialities are and have been the best on the market. Where is the Gardener who does not pin his faith to one or the other of these celebrated Insecticides or Fertilisers? XL ALL FERTILISER has pleased all who have used it this season. The Sales of XL ALL FUMIGATOR prove that it is more popular than ever. XL ALL LIQUID NICOTINE INSECTICIDE is always spoken of by gardeners and growers as the most deadly to Mealy Bug, Thrip, etc. XL ALL WINTER WASH for dormant Trees acts like magic, clearing the Trees and Bushes of all Insects' Eggs, Moss, and Fungoid Growths. XL ALL LAWN SAND, a weed eradicator and fertiliser for weedy and poor lawns. XL ALL WEED KILLER used once a year "No weeds can live." Please ask your Nurseryman, Seedsman, or Florist for a copy of my small pink list, giving particulars of these and many other XL ALL Preparations which can be obtained from the Horticultural Trade throughout the World. G. H. RICHARDS, Manufacturer and Patentee, 234 Borough High Street, London, S.E.

TWERTON HILL NURSERY, BATH.

THE BEAUTIFUL BURMESE LILY,

LILIUM SULPHUREUM.

WE do not claim to be recognised bulb importers, our trade being confined principally to Orchids. Our collector has for some years sent small consignments of this Lilium, which have been distributed amongst our orchid customers. So many enquiries came to hand during their last flowering season from gentlemen who had seen them in various places, we instructed our collector to make an effort to send us a good consignment. These bulbs come from such a remote part, that unless collected in conjunction with orchids, they cannot be placed on the market at a price likely to be popular, hence this lovely Lilium has hitherto remained in the background. The consignment now to hand consists of a magnificent lot of bulbs, all in sound, perfect condition. The handsome flowers are borne many on a stem, very large, often measuring 10 inches in length. The colour is of a bright sulphur yellow, toning to creamy white towards the edges. Deliciously perfumed, the substance of the flower is remarkable. Very free in habit, even the smallest bulbs flower well. For autumn decorative work it is invaluable.

Treatment. It must not be supposed because this Lilium originates in Burma that it requires warm treatment; it is found high up on the hills. In a good sunny position it will thrive and flower well in the outside gardens of the Midlands and South of England, and although we have seen it flower well outside in the North, a bad summer might cause the flowers to come late. For the North it is best to grow them in pots, starting in a cool airy house, bedding the pots outside during the summer months, and removing into the house if necessary to flower. If required earlier in the South they can be started in the same way; a house where geraniums are wintered is very suitable. They like a mixture of loam, peat, and sand, and a nice light position in the house.

For the purpose of making the widest possible distribution of these Bulbs not more than 12 will be supplied to each Customer.

A.—Good Bulbs	7 inches in circumference,	**1/6** each;	3 for **4/-**;	12 for **15/-**
B.—Fine Bulbs	8 and 9 ,, ,, ...	**2/-** ,,	3 ,, **5/-**;	12 ,, **19/-**
C.—Very Fine Bulbs	10 ,, ,,	**3/-** ,,	3 ,, **8/-**;	12 ,, **30/-**

SUTTON'S PRIMULAS.

INDISPENSABLE
FOR
WINTER
DECORATIVE
WORK.

A SECTION OF ONE OF THE PRIMULA HOUSES AT READING.

SINGLE.

The Duchess. One of the most beautiful Primulas yet raised. Large pure white flower, with unique zone of rosy-carmine surrounding a clear yellow eye. Per packet, 2/6

The Czar. A rich violet-blue colour. Per packet, 2/6

Crimson King. The darkest crimson Primula in existence. Per packet, 2/6

Superb, mixed. Including all the finest singles of the plain-leaved class. Per packet, 3/6

Rosy Queen (Fern-leaved). A most charming pink, of elegant habit. Per packet, 2/6

Lavender (Fern-leaved). Large flowers of a pretty lavender shade, edged with white. Per packet, 2/6

GIANT.

Giant Pink. The finest Primula in all the Giant section, petals extremely large and of great substance. The delicate carmine-pink colour is particularly valuable for indoor decoration. Per packet, 3/6

Giant White. Remarkable for the size, substance and purity of the flowers. Per packet, 3/6

Giant Salmon Pink. (TERRA COTTA.) A distinct and valuable addition to our Giant Primulas. Per packet, 3/6

Giant, mixed. Including the named varieties and many others, which, though true Giants, do not come sufficiently true from seed to be offered separately. Per packet 3/6

STELLATA.

White Star. The original variety. Pure white flowers produced in abundance. Per packet, 2/6

Light Blue Star. A delicate porcelain blue shade. Per packet, 2/6

Ruby Star. By far the darkest and richest coloured Star Primula yet introduced. Per packet, 2/6

Pink Star. A charming companion to the white variety. Per packet, 2/6

Giant Star. Flowers of the true Star type, but as large as those of the fringed forms of P. sinensis. White and carmine, each per packet, 2/6

Mixed Star. Per packet, 2/6

THE GARDENERS' MAGAZINE.

NOTES OF THE WEEK.

Soil Inoculation.

There are unquestionable proofs that for a period of 2,000 years at least cultivators have been familiar with the fact that a leguminous crop has so beneficial an effect upon the soil as to greatly improve it for the succeeding crop. There is also evidence that they gave practical effect to their knowledge. Pliny, in dealing with the field bean in his "Natural History" (Book XVIII.), writes: "It fertilises the ground in which it has been sown, as well as any manure"; hence, he continues, "in the neighbourhood of Thessaly and Macedonia, as soon as it begins to blossom they turn up the soil." In other words, they ploughed in the plants for the enrichment of the soil, in much the same manner as it has been done in this and other countries in modern times. This beneficent action of the leguminous plants gave rise to considerable speculation on the part of those not accustomed to take a superficial view of things; and it was conjectured by some that they enriched the soil, taking fertilising matter from the atmosphere and conveying it to the soil by means of the roots in process of decay. It was not, however, until the middle of the last century that the beneficial effect of these plants upon the soil was investigated on scientific lines. Boussingault gave his attention to the matter, and in 1854 he submitted his views thereon, and these were to the effect that the only source from which plants could derive their supplies of nitrogen was the fixed nitrogen in the soil. Gilbert and Lawes supported Boussingault, and it was not until some thirty years later that Hellreigel was able to demonstrate, as the result of his researches, that leguminous plants did obtain the nitrogen necessary to their growth from the free nitrogen of the air. Two years later Wilfarth was able to show that these plants could be successfully grown in soil free from nitrogenous matter, provided their roots were well furnished with nodules. About the same time as Wilfarth was able to publish the results of his researches Beijerinck was successful in isolating a bacterium found in the nodules, which he named Bacillus radicicola, and is now known as Pseudomonas radicicola. Since then other scientists have been busily engaged in investigating this beneficent organism, and these investigations had not proceeded far before it was felt that if soils more or less deficient of this bacterium could be inoculated therewith, it would be an enormous gain to cultivators. As so well known, nitrogen is one of the most important constituents of plant food, and the materials from which it is derived are the most costly of fertilisers. Hellreigel, Nobbe, and other investigators have demonstrated the possibility of this being done, but much more has to be accomplished before conclusive evidence can be obtained as to the conditions under which soil inoculation can be the most successfully effected. In the earliest experiments newly-reclaimed land was inoculated by soil obtained from land on which a leguminous crop had been grown, and the results were considered satisfactory. On the other hand, cultivated land inoculated in a similar manner gave results of a negative character. The removal of any considerable quantity of soil from one place to another is a costly matter, and to provide a means by which soil might be inoculated in a less troublesome and expensive manner, Nobbe and Hiltner directed their attention to the preparation of a pure culture for distribution in the ordinary way of business among cultivators. This culture was introduced under the name of Nitragin, but it was less successful than was anticipated. It has, we understand been since improved. In America considerable attention has been devoted to soil inoculation by means of pure cultures, but the reports on their use indicate the necessity for further trials. More recently Professor Bottomley, of King's College, London, has become impressed with the importance of soil inoculation as a means of increasing the productiveness of soils deficient in bacteria, and two years ago he introduced a culture under the distinctive title of Nitro-bacterine. This has been widely distributed, and a considerable diversity of opinion has been expressed with regard to its value. Consequently, the results of the experiment that was carried out in the Wisley Gardens of the Royal Horticultural Society last year are of special interest. The experiment was conducted by Mr. F. J. Chittenden, F.L.S., the director of the Wisley Laboratory, and the report is published in the current issue of the society's "Journal." The conditions under which the experiment was carried out appear to us to have been most favourable, for the soil of the gardens is light and sandy, and deficient in humus, as compared with a highly cultivated garden. We learn from the report that one-half of the ground set apart for the experiment had for the previous four years received ordinary garden cultivation, the crop in 1907 having been celery. The other half had not carried a crop in the previous year, and the two parts were

MR. R. L. HARROW.

divided by a broad path. Each half of the area was divided into twelve equal plots, each having an area of two rods. Culinary peas were selected for the purposes of the experiment, and the varieties were Ne Plus Ultra, Duke of Albany, Telegraph, and Maincrop, and it is unfortunate that a considerable number of the plants of the last-named failed to make a satisfactory growth. In the report the number of pods, and the weight of the pods and the peas are given, and the counting and weighing of the produce must have been a serious business, but it is only by such method of procedure that a clear idea can be obtained of the results of an experiment. It is not possible here to do more than briefly refer to the totals. Table A shows that in the first two unmanured plots there was, in the case of the inoculated soil, a percentage decrease of 3 grammes in the weight of the pods, and of 4 grammes in the weight of the seeds. The plots included in Table B were not manured or inoculated, but the seed in one plot was inoculated, and here there was a percentage decrease of 23 grammes in the weight of pods, and of 21 grammes in the weight of seed. Table C, devoted to the plots which received a dressing of manure at the rate of 10 tons per acre, shows a percentage increase of 6 grammes in the weight of pods, and 5 grammes in the weight of peas. The plots included in Table D received a dressing of lime, and here the weight of pods was practically equal, but there was a percentage increase in the weight of peas of 4 grammes in favour of the inoculated plot. Table E shows that with a dressing of lime, kainit, and superphosphate, there was a percentage decrease in the produce of the inoculated plot of 14 grammes in the weight of pods, and of 16 grammes in the weight of seeds. Table F shows that with a dressing of calcium cyanamide there was a percentage decrease of 2 grammes in the weight of pods, and an increase of 3 grammes in the weight of peas. The inoculated plots on the fallow land that had not been manured gave much better results. Table H shows that with inoculated soil and seed, the percentage increase was 10 grammes in the weight of pods, and 14 grammes in the weight of peas. The treated plot included in Table I had simply the seed inoculated, and this gave a percentage increases of 13 grammes and 17 grammes. Table K contains the results of the soil manured and the seed inoculated, and this shows considerable decreases, and Table L is devoted to the results obtained with the addition of a dressing of lime, but owing to the difference in the number of plants in some of the rows there is no occasion to quote the figures. In the aggregate there was scarcely any difference in the produce of the two sets of plots, and therefore the results obtained at Wisley must be regarded as negative.

Mr. R. L. Harrow, whose portrait we have the pleasure of giving in this issue, has for some years past been at the head of the practical side of the work of the Royal Botanic Gardens, Edinburgh, and has, by his remarkable ability and courtesy, won golden opinions from those who have had opportunities for becoming acquainted with the judgment he displays in the discharge of his duties. Some eighteen years ago Mr. Harrow was, after occupying the position of sub-foreman in the Royal Gardens, Kew, appointed to the charge of the glass department at Edinburgh, and in this position he achieved so high a degree of success that when, some years later, Mr. A. D. Richardson retired from the curatorship, Mr. Harrow was appointed to the important position he now holds. As befits the occupant of a position involving the discharge of duties of the most diverse character, Mr. Harrow is fully conversant with the various classes of plants, trees, and shrubs that have a place in a botanic garden of the highest class, but his knowledge of the many plants from tropical and temperate regions is quite remarkable; especially is this made evident by the splendid condition of the occupants of the fine structures that form so distinct and interesting a feature of the Edinburgh establishment.

Sweet Pea Annual and Schedule for 1909.—Mr. Charles H. Curtis, hon. secretary of the National Sweet Pea Society, asks us to state that the Sweet Pea Annual and Schedule for 1909 will be ready during the present week. The despatch of copies will commence on Wednesday, and any member not receiving a copy by the end of the week should notify the hon. secretary at once. The "Annual" will this year be sent to non-members for 2s. post free, not 1s. 3d. as hitherto. The London exhibition will be held on July 23, and the provincial show at Saltaire on July 13. A new and complete catalogue of sweet pea names and descriptions will be ready about the end of February, and all new members joining the society for 1909 will receive a copy gratis; it will be sold at 6d. per copy.

Cornish Gardens.—In the issues for February 6 and 13 we shall give an illustrated account of some of the more famous of the many fine gardens in Cornwall. The gardens that will be described and illustrated will include those of Bosahan, Pencarrow, Prideaux Place, Tregye, and Trevarrick.

Glastonbury Thorn (Cratægus monogyna, var. præcox).—The sacred legend which is associated with the flowering of this thorn in midwinter always gives the tree a peculiar interest to the general public. There is a specimen of it growing in the Thorn Avenue at Kew (South of the Temperate House) which does not flower regularly in midwinter. Mr. W. J. Bean, writes in the "Kew Bulletin," that with a mild November and December such as is frequently experienced, it will flower about Old Christmas Day (January 6), but if cold weather sets in before the New Year the flowers may not open until March or April. This season, however, they have been extraordinarily early. The tree was in full blossom in the first week of November, before any leaves had fallen. This was no doubt accounted for by the unusual warmth of the past autumn. In addition to these early blossoms, the Glastonbury thorn at Kew always bears others at the normal flowering time of the species—May and June—and from them a crop of haws is developed. This tree was, in November, 1908, carrying flowers, fruit, and full foliage simultaneously.

National Chrysanthemum Society.—The annual meeting of this society will be held at Essex Hall, Essex Street, Strand, on Monday next, February 1. Sir Albert Rollit, president, will take the chair at 7 p.m. We are pleased to learn from the report that an improvement in the financial position of the society has been effected during the past year. The report states, "It will be observed from the statement of assets and liabilities that the society's finances show a considerable improvement when compared with the previous year. The surplus of assets over liabilities has been increased during the year under review from £53 15s. 1d. to £10 18s. 9d., which will more than enable the committee to carry out the policy set forth in the last report of retransferring £25 to reserve account from the year's income. The committee will continue to keep a careful watch, in advance, on the society's finances, as the great importance of having a reserve to fall back upon becomes increasingly obvious every day."

Cider Vintage of 1908.—In an interesting communication to the "Times" Mr. C. W. Radcliffe Cook writes with reference to the ciders of last year's make that, although they have not quite come up to the expectation that was formed of them before cidermaking began, they will, on the whole, be of good quality. The display of blossom was magnificent, and gave promise of a bumper crop; but spring frosts and violent and bitter winds just as the young foliage was breaking gave the trees a check, from which some of them never quite recovered. The inclemency of the weather at the period in question seems to have been more felt in the west Midland counties than in the south-western. In the former, a considerable quantity of fruit fell from the trees during the heat of summer, leaving about half a full crop; whereas in the latter two-thirds of a crop was obtained, and in some parts, especially in Devonshire, a full crop. The prolonged spell of drought in the summer, when the fruit should have been swelling, retarded its growth; and in the late autumn, when it should have been ripening, the rains caused it to start growing again. This, with the absence of sun, caused the juice to be somewhat deficient in sugar, while it contained rather more than the average percentage of acid and rather less than the average percentage of tannin. Some of the best varieties, especially the later sorts, were, however, less adversely affected by climatic influences than those of inferior grades: and the analysis of the juice of some of the former kinds made at the National Fruit and Cider Institute has shown an astonishingly high specific gravity due to a preponderance of saccharine ingredients, so that the ciders made from such varieties will probably be full bodied and of fine flavour. Taking, therefore, the apple crop all round, we may come to the satisfactory conclusion that the vintage of 1908, though not a grand vintage, will be abundant in quantity, and above the average in quality, in the latter respect resembling somewhat the vintage of 1905.

Perpetual-Flowering Carnation Society.—The annual general meeting of this society will be held in the Hotel Windsor, Victoria Street, London, S.W., Wednesday, February 10, at 4 p.m., and the spring show at the R.H.S. Hall, Vincent Square, on March 24.

Horticultural Club.—The annual meeting of the Horticultural Club will be held at the Hotel Windsor on February at 5.30 p.m. This will be followed by the annual dinner at the same hotel at 5 p.m. Sir Frank Crisp has kindly undertaken to provide the music, and as a larger attendance than usual is expected, members and their friends are advised to inform the honorary secretary of their intention to be present as early as possible. No seats, we are informed, can be reserved after February 4.

Italian Gardens.—At a meeting of the Italian Circle of the Lyceum Club, Mr. Joseph Cheal, of Crawley, gave a lecture, illustrated by lantern slides, on the "Old Gardens of Italy." The Italian love of gardening, Mr. Cheal pointed out, dated from an early period. Roman generals, no doubt, brought home marvellous tales of the gardens of Assyria, Babylonia, and Egypt, and it was probably this that fired the imagination of Lucullus, whose magnificent garden at Naples is described by Pompey. The Emperor Hadrian, early in the second century, seemed to have stimulated the taste for horticulture, and Pliny the younger, about the same time, not only designed gardens, but had left descriptions of some of the gardens of the period. For several centuries during the decline of the Roman power the love of gardening also declined. There was a great revival in this direction, however, about the close of the fourteenth century. A great impetus to gardening seemed to have been given by Lorenzo de Medici, a friend of Michael Angelo, and his family had much to do with the creation of the beautiful villas and gardens around Rome and Florence. Zoological specimens were also introduced into gardens and parks, which were stocked with choice specimens of birds and animals. During the period of the Renaissance, Senators and others and Church dignitaries seemed to have vied with each other in the making of gardens, many of which could be seen to-day, some in varying stages of decay, others still maintained and preserved with great care.

New Open Space for Bristol. Mr. G. A. Wills has acquired 73 acres, the property of the Leigh Woods Land Company, Clifton, including the famous Nightingale Valley, for preservation for the public use.

Erfurt, the Flower City.—The United States Consul at Weimar, Mr. W. L. Lowrie, writing about the German seed and plant trade, tells us that the soil about Erfurt is especially adapted to the culture of vegetables and plants. It is deep, rich, and well watered. The annual rainfall is heavy, and the surrounding hills afford good protection from the cool winds which sometimes sweep down from the Thuringerwald. There are 108 concerns engaged in the seed industry, also 35 seed exporters and 24 florists. An idea of the extent of this business may be gained from the area of glass employed. The total is 113,735 square metres (the square metre equals 10.764 square feet), of which 30,867 square metres cover propagating houses and 82,858 square metres are used over specially fertilised beds. Nearly 3,000 people are employed in various capacities. While there are no statistics available in regard to the total annual output of the Erfurt seed and plant concerns, a single firm produces each year 70,000 to 80.000 cyclamens. 100,000 lilies of the valley. 60.000 apples in pots. 20.000 pears. 10.000 plum, apricot, peach, and quince plants, 30,000 strawberry plants, 300,000 short-stemmed and 40.000 long-stemmed roses. This concern has a dozen large hothouses and salesrooms, packing rooms, a blacksmith shop, a carpenter shop, and a bindery where the cut flowers are arranged and the dried plants and mosses are put together in wreaths or bundles. Garden products grown in Erfurt may not be peddled in the city.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

The sixty-ninth annual general meeting of this institution was held on Thursday, January 21, at "Simpson's," 101, Strand. There was a good attendance, and Mr. H. J. Veitch, V.M.H., presided. More than usual interest was evinced in this meeting because since the last meeting the Old Age Pension Act has come into force, and there was no little speculation as to the effect the provisions of this Act might have upon the institution, and also what steps the committee proposed to take with regard to them.

Those present included Messrs. A. W. Sutton, J. Hudson, G. Wythes, Owen Thomas, P. Veitch, A. Dean, J. McIndoe, G. Monro, W. Iceton, W. Bates, W. Denning, W. James, D. Ingamells, J. Wheeler, G. Gordon, C. Fielder, W. Barr, A. White, A. Paul, J. Jefferies, etc., etc.

CYCLAMEN SUTTON'S GIANT WHITE.

One of the many finely-flowered plants of the superb strain of large-flowered cyclamen, exhibited by Messrs. Sutton and Sons at the Royal Horticultural Society's Meeting on Tuesday last.

After the usual formal proceedings, the Secretary, Mr. G. J. Ingram, read the report of the committee for the year 1908. The following is the report abridged:—

COMMITTEE'S REPORT FOR 1908.

The charity has been in existence seventy years, it has distributed in permanent and temporary help upwards of £125,000, and at no other period in its history has it done so much in the way of assisting the necessitous and suffering as in the year now under review.

At the commencement of 1908, 231 persons—133 men and 98 widows—were receiving yearly allowances amounting in the aggregate to over £4,000. During the year sixteen (eleven men and five widows) have passed away; of the men, four left widows, who, being necessitous and in every way deserving, were at once placed on the funds without election, under Rule III. 10, to receive the widow's allowance of £16 a year. In addition to those who died, one widow has gone to Australia to reside with her son, and another widow has been removed to an infirmary by medical orders. There were therefore at the close of the year 217 persons on the funds, and the committee recommend for election this day eighteen candidates from an approved list of seventy-three applicants. Although the number of beneficiaries will thus be increased to 235, or four more than at the corresponding period of last year, the committee deeply regret their inability to recommend a larger number, the more so as the claims for help are more numerous than ever before—the list of applicants this year showing an increase of twenty on that at any previous election. The two special funds, the "Victorian Era Fund" and the "Good Samaritan Fund," still prove of the utmost value and usefulness by the timely help they afford.

The annual festival dinner, which took place at the Hotel Metropole in June last, under the presidency of the Right Hon. Lord Aldenham, was most successful, and the committee take this opportunity of tendering their grateful thanks to his lordship for his warm and sympathetic advocacy of the objects and aims of the charity as well as its needs. They also desire to offer their sincere thanks to those gentlemen who acted as stewards or collectors; to the horticultural Press; to the donors of flowers; to those who decorated the tables, and to other friends who helped to secure the success of the festival. The committee have further to express their gratitude to those who have so kindly allowed their beautiful gardens to be opened to the public for the benefit of the funds of the institution, notably the Right Hon. Earl Beauchamp (Madresfield), Lord Northbourne (Betteshanger), Mary Countess of Ilchester (Holland House), the Lady Battersea (Overstrand), Sir Frank Crisp (Friar Park), and E. J. Wythes, Esq. (Epping); thanks are also due to Messrs. Fisher, Son, and Sibray, Lim., for opening the Royal Nurseries at Handsworth for the same purpose; the committee are also indebted to the Messrs. Geo. Monro Concert Committee for again most kindly allocating a portion of the proceeds derived from their well-known and successful annual concert.

With much gratification the committee refer to the generous kindness of N. N. Sherwood, Esq., for his gift of £25 for unsuccessful and needy applicants; to Arthur W. Sutton, Esq., for kindly giving a year's allowance of £20 for an applicant suffering from incurable paralysis; and to George Monro, Esq., for his kind contribution of £16 towards the maintenance of an aged widow. The recipients were truly grateful for these unexpected bounties.

The services of the honorary treasurers and honorary secretaries of the several auxiliaries are keenly appreciated, and the committee gladly place on record their indebtedness for the kind and valued efforts of the following gentlemen on behalf of the work, viz.:—

Bristol and Bath.—Col. H. Cary Batton, president; W. A. Garaway, Esq., hon. treasurer; and Mr. George Harris, hon. secretary.

Worcester.—Right Hon. Earl Beauchamp, K.C.M.G., president; Mr. John White, hon. treasurer; and Mr. Percy G. White, hon. secretary.

Devon and Exeter.—C. R. Collins, Esq., president; and Mr. W. Mackay, hon. treasurer and secretary.

Wolverhampton.—C. T. Mander, Esq., J.P., president; Mr. Bradley, hon. treasurer; and Mr. Tom B. Dobbs, hon. secretary.

Berkshire, Reading, and District.—Mrs. Rowland Spurling, president; Arthur W. Sutton, Esq., J.P., V.M.H., hon. treasurer; and Mr. L. Castle, hon. secretary.

Liverpool Auxiliary.—The Right Hon. the Earl of Derby, president; A. J. Crippin, Esq., hon. treasurer; and R. G. Waterman, Esq., hon. secretary.

It is with much pleasure the committee announce that Lionel de Rothschild, Esq., has kindly consented to preside at the seventieth anniversary festival dinner in aid of the funds at the Hotel Metropole, on Wednesday, June 23 next. They have also to report that George W. F. Macnaughton, Esq., M.D., M.R.C.P., has kindly consented to accept the office of honorary physician to the institution.

With regard to the Government Old Age Pension Act, it will be seen that the honorary solicitor has given notice of motion to be submitted to the subscribers at the meeting this day. Its intention (if the subscribers see fit to adopt it) is to enable the committee to act under Rule III. 6, should circumstances render it necessary and desirable to do so, without, however, causing any pecuniary loss to the beneficiary or applicant for help; and the committee would point out that of those now applying through incapacity and distress, there are forty-one whose ages alone render them ineligible for the benefit of State aid. The importance, therefore, of continued support to the institution is thus manifest.

In conclusion, the committee most earnestly appeal for increased means for this national horticultural charity, which for seventy years has carried on its beneficent work with such comfort and help to the recipients of its benefits as cannot be overstated.

Harry J. Veitch, Esq.,
Treasurer and Chairman of Committee.
George J. Ingram, Secretary.

FINANCE.

BALANCE SHEET FOR YEAR ENDING DECEMBER 31, 1908.

Income.

	£	s.	d.
To Balance	£1,129	9	6
Amount on deposit	3,880	0	0
Annual subscriptions	1,434	0	6
Donations at and in consequence of Festival Dinner, including special gifts	1,954	17	10
Legacies—			
Mrs. A. H. Lewis-Hill, with interest	1,007	4	5
Mr. B. Greaves	50	0	0
Return of Income Tax	42	18	6
Dividends and Interest	880	0	10
	£10,378	11	7

Expenditure.

	£	s.	d.
By Pensions and gratuities, including special gifts from Messrs. Sherwood, Sutton, and Munro	£4,039	12	0
Expenses of annual meeting and election	10	3	4
Rent, firing, lighting and salaries of Secretary and Clerk	566	9	7
Printing (less Advertisements)	80	11	8
Expenses of Festival Dinner (less dinner charges)	54	13	0
Postages, telegrams, repairs, etc.	78	9	6
Placed on deposit	3,530	0	0
ditto Mrs. Lewis-Hill's legacy	1,007	4	5
Balance with Treasurer	999	8	4
Balance with Secretary	11	19	9
	£10,378	11	7

	£408	6	7
By Gratuities	£101	10	0
Balance in hand, December 31, 1908	306	16	7
	£408	6	7

Mr. Harry J. Veitch moved the adoption of the report, and in so doing said that the institution was making steady progress. He also referred to the legacies received during the past year, and urged that friends when making their wills would remember the institution, so that more suffering and aged gardeners might be assisted. Mr. Roupell formally seconded the motion, and it was unanimously adopted.

Mr. A. W. Sutton moved the thanks of the meeting to Mr. Harry J. Veitch for his services as chairman and treasurer, and his re-election to those positions. Mr. Sutton referred to Mr. Veitch as the "friend of gardeners." Mr. Alex. Dean seconded the motion, and it was heartily adopted. On the motion of Mr. G. Monro and Mr. Wheeler, Mr. G. J. Ingram was unanimously re-elected secretary of the institution, and his able services were eulogised by each gentleman. Mr. Ingram suitably replied.

Mr. R. G. Waterman proposed that Messrs. E. T. Cook, D. Fleming, J. Jennings, J. McIndoe, F. W. Moore, A. W. Sutton, Owen Thomas, Bailey Wadds, and George Woodward be re-elected as members of committee, and that Mr. Fred Cooper be elected in place of Mr. R. Millican Hogg, resigned; carried. On the motion of Mr. Wythes and Mr. C. Fielder, Messrs. T. Manning and T. Swift were heartily re-elected auditors of the institution's accounts. The old arbitrators were also again re-elected on the motion of Mr. O. Thomas and Mr. E. T. Cook.

Mr. White, in the absence of Mr. W. A. Bilney (through illness) formally moved:—"That every person having attained the age of seventy years who is in receipt of an annuity from the institution, and is eligible for a Government Old Age Pension of less than the maximum allowance of 5s. per week, or whose total income does not exceed £31 10s. per annum, may have such charitable annuity reduced as the committee may determine under Rule III. 6, so as to render him or her eligible to apply for a pension on the Government scale, provided always that such reduction does not involve the beneficiary in any pecuniary loss," and said he thought few would be against this proposal, which would permit the committee to extend the benefits of the institution without in any way causing a loss to present annuitants. Mr. D. Denning seconded the motion. Mr. Sutton, Mr. Dean, and Mr. Monro all spoke to the motion, the former suggesting the deletion of the word "charitable" before "annuity." Mr. Owen Thomas also spoke, and the motion was carried with the deletion already referred to. The committee will now meet and fully consider the whole subject of old age pensions as far as they apply to the institution, and will publish the decisions arrived at in due course in the horticultural Press.

Mr. Cooper and Mr. G. Monro were appointed scrutineers of the ballot, and the Chairman announced that Mr. A. W. Sutton had kindly promised to renew his donation of a pension to one of the most deserving of the unsuccessful candidates.

ELECTION OF PENSIONERS.

The declaration of the poll took place rather later than usual. The successful candidates were Emma J. Whitehurst, J. G. Anstey, Matilda Ings, H. Heims, Thomas Jones, J. Burton, H. Cooper, Wm. Gardiner, Jane Noble, Harriett Helman, Wm. Cope, H. Gage, T. C. Cushion, Ed. Tibbles, G. Lawrence, J. Throp, J. Talmage, Wm. Reynolds. These were declared duly elected, and then it was proposed by Mr. H. J. Veitch, seconded by Mr. G. Monro, and carried, that Nancy Wright and James Young be placed on the funds without election. It was notified that W. J. Williams would receive the pension given by Mr. A. W. Sutton, and Laura Stockwell, a candidate both very poor and very ill (not on the list of candidates) would receive Mr. Monro's donation.

The meeting closed with votes of thanks to the scrutineers and chairman.

FRIENDLY SUPPER.

Very soon after the declaration of the poll the annual friendly supper was held, under the presidency of Mr. W. J. Jefferies. After supper there were the usual loyal toasts, and a few other toasts and speeches, and all the speakers were commendably brief.

The Chairman, in proposing "Success to the Institution," referred to the great benefits it conferred on the old and disabled, but he threw the responsibility of advocating the claims of the institution upon Mr. Harry J. Veitch, who said he had responded more than forty times to a similar toast, and therefore could not be expected to say anything new. Mr. Veitch briefly reviewed the work of the institution, referred to some special cases that had been relieved, and thanked all who had helped, and in his inimitable manner invited increased support. Mr. Veitch's remark that every one was pleased to see Mr. N. N. Sherwood back among them again, was thoroughly endorsed by the company, and when Mr. Sherwood rose he received quite an ovation. With all his old breeziness and jollity Mr. Sherwood acknowledged the welcome, but there was an added touch of sympathy and kindliness to suffering humanity in his remarks that materialised in a promise to provide pensions this year for two deserving unsuccessful candidates. This promise was given as a thank-offering for return to health, and as a part of the doctrine he believed in and endeavoured to act up to, i.e., of doing at least one good turn each day to someone. Needless to say, those present showed their appreciation of Mr. Sherwood's generosity.

Mr. W. Atkinson proposed "The Chairman"; Mr. G. Bunyard, V.M.H., "The Committee and Country Friends," to which Mr. G. Monro and Mr. R. G. Waterman (the Liverpool correspondent) replied. Mr. G. J. Ingram made a capital little speech in response to the toast of his health, and some little amusement was caused by the Chairman calling upon four horticultural pressmen present to respond to "The Press."

PENZANCE BRIARS.

Whether rose lovers have shown their appreciation of the endeavours of the late Lord Penzance to enhance the attractions of the flower garden by planting as freely as they should have done the beautiful briars that he was successful in creating, is an open question. I am inclined to the opinion they have not done so, for many are the gardens that might be visited in which they are wholly unrepresented. They are not, of course, so useful for small beds and borders as are roses of moderate growth, such as the hybrid perpetuals and hybrid teas; but there are few gardens in which suitable positions cannot be found for some of them. This being so, I would advise those who love roses to have a look round, with a view to finding positions for a few of the best. For the information of those who know but little or anything of the Penzance briars, it may be useful to point out that they are robust in growth, have fragrant leaves, and exquisitely coloured flowers, and are free in blooming. The illustration herewith of Rose Bradwardine gives an excellent idea of the form of the flowers and of the manner in which they are borne, but it must be pointed out that they are shown below the natural size.

The manner of disposing them in the pleasure grounds must be determined by the area, the contour, and other considerations. Bold groups on a closely shaven lawn, and within a short distance of the residence will not appear out of place, but they produce a more pleasing effect when they are assigned a place in a less highly-dressed part of the pleasure grounds. They certainly add considerably to the attractions of the wild garden when planted in open sunny positions and given the small amount of attention necessary to maintain them in a healthy state, and to keep them free from a superabundance of old wood. Highly effective groups may be formed by planting them in threes, each triple consisting of one variety. When so planted they should be arranged in the form of a triangle, with eighteen inch sides. If larger groups are required the number of plants may be increased to five or more, and a proportionately larger space allowed them. They are admirably adapted for hedges and screens, and in many cases they may be used instead of the commoner shrubs for the purpose of separating one part of the garden from the other. When utilised in the formation of screens and hedges they should be arranged eighteen inches apart in a single row.

Previous to planting the soil should be well prepared by deep digging and moderate manuring, and in planting the soil should be trodden very firmly about the roots. Very little pruning is required by the Penzance briars. It is a good rule to cut the whole of the growths to within ten inches or so of the ground level early in the first spring after planting. Subsequently the pruning should be limited to the removal of old and useless wood. Should the bushes become somewhat bare and unsightly at the base, as they sometimes do, cut them hard back to obtain new growth from near the base, or destroy them and form fresh clumps with new plants, and, as far as practicable, in new positions. All the varieties in cultivation are well worth growing, but for the guidance of those whose space is limited, I would suggest the following as being especially desirable: Anne of Geierstein, rose-crimson; Amy Robsart, rich rose; Edith Bellenden, soft pink; Jeannie Deans, rose-crimson; Julia Mannering, bright pink; Lucy Bertram, bright crimson; and Rose Bradwardine, bright rose-pink.

VIATOR.

PENZANCE BRIAR ROSE BRADWARDINE.
Flowers bright rose-pink.

TOWN GARDENING.

No less a distinguished critic than Maurice Maeterlinck has recently turned his attention to town and city gardens as they exist at the present day in this country.

He condemns in a certain measure the majority of these gardens, especially in regard to those formed during recent years, and vividly describes one of these creations, "the winding paths that lead nowhere, the inevitable lake, the indispensable lawn, the useless mounds and valleys, and the everlasting flower beds," as "paltry and monotonous combinations."

There is, possibly, need for this criticism, and we rather welcome it, especially coming from so gifted a writer, but in the finding of a substitute for this state of affairs we are offered either the "French or Italian garden," or the "very forest itself." To my mind, the task set before town and city gardeners in the planting of open spaces is far from being an easy one. As a rule many things have to be taken into consideration, and one need not wonder why the general run of town gardens have something in common. In the effort to provide gardens in towns that shall combine in their entirety "a playground for the children," "shady walks and shelters for the aged," "flowers for those who are denied the country," and to make the most natural and undulating picture possible, the town gardener is forced to ring the changes upon the very features which are roundly condemned, and should he in his difficulty, produce a garden similar in style to the one in the next town, one should at least regard him in no unkindly mood for having solved his problem in the same way as others in the same position.

It has been suggested that town gardens should be in complete harmony with the adjacent buildings, and in considering the suggestion one wonders if this would not make for the monotony which M. Maeterlinck decries. Ofttimes a daring subtle contrast will effect the miraculous in the garden, and will give pleasure and delight where a formal arrangement would repeat itself until it becomes wearisome to the eye. I am not in favour of gaudy colour effects, or of hastily planned gardens, but one thing is apparent, that a decided contrast will emphasise the lines and graces of any two given objects. That is why well-grown foliage upon a house front is so pleasing. There is no greater contrast than stone and brick walls and green foliage, and yet how admirably the result justifies the blending of the two.

Ivies, vitis, clematis, magnolias, roses, and a score of kindred subjects will immensely improve the appearance of walls, and in the same manner will carefully-chosen trees, flowers, and shrubs create charming effects in the open spaces of our towns. I would not endeavour to minimise the work of the town gardener. He is far more limited in his choice of subjects than his brother in the countryside. He is usually limited in space, and also has to contend with architectural ugliness. And one can well understand that to arrange a town garden in a thoroughly satisfactory manner will call for the artist's eye and the practical man's knowledge.

Not that well-conceived town gardens are an exception, for there are many wherein simplicity of design is combined with natural beauty of the subjects used, but the idea which I want to bring into prominence is that he who would be successful in this phase of gardening must devote himself to the thorough mastery of his work, for it is a subject which will call for as much study and thought as the architecture of the houses themselves.

The planting of trees in the streets of our towns should also be carefully considered. This is gradually extending among those who have the making of the towns, but much more might be done in this direction. Limes are popular and effective, and are very suitable for street planting. Chestnuts also are very good, and beautiful when in blossom. Elms make wonderful avenues, especially when used in conjunction with large buildings which stand well back in their own grounds, but are very treacherous as they age. Planes and maples also furnish useful material for town planting, but one would naturally ask why not widen the range, and utilise as street trees those favourite flowering trees which are seen in many town gardens.

Especially do my remarks apply to the almond, the cherry, the laburnum, the thorns or cratægus, the acacias, and the mespilus. And a word for those delightfully coloured subjects, the bronze and purple beeches, and Prunus Pissardi.

Our English gardens, arranged in a natural style, have been spoken of as "being adapted from China and Japan," though why they should be so described is difficult to understand.

Certainly we have gained much from the gardens of the Celestial Empire, and the Flowery Land, both in floral wealth and in ideas, and we are grateful to the gardens of the East for yielding up their treasures to us, though why a "natural" garden should be considered a derivative from the Far East I certainly fail to see.

It is, however, to the country garden that we can apply our Japanese ideas, for in these there is more scope for those delightful iris gardens, those exquisite lily pools, those dainty wistaria-clad tea-houses, those trinkling rills margined with primulas, and those lovely sweeps of bamboos, and stretches of lilies, and one can reproduce them in our country gardens, or harmonise them with more typically English effects

But to the town gardener one is compelled to give a word of cheer. After all there is nothing like foliage and flowers, either inside or outside of a town house. They are the representatives of the open country beyond, they speak with no uncertain voice of the breeze-blown hills, the flower-clad vales, the shady forest, and the azure skies, and cheer the toiler and the town dweller with their message from Nature and the wilds.

In conclusion, the more we foster the town gardener's art, the further we emphasise the value of town planting upon our municipal authorities; and the further we spread the knowledge and the love of flowers and trees among the rising generation, the better, happier, and healthier will town life become. P. S. Hayward.

WEATHER AT ROTHAMSTED IN 1908.

The meteorological records of the Rothamsted Experimental Station, Hertfordshire, for 1908 show that the year was characterised by a deficiency of rain, as was that of the previous year, 1907. There were but three months of excessive rainfall, and nine months showed a deficiency. The number of rainy days were, however, 184, being 12 days in excess of the average of the past 55 years.

The mean temperature of the year was slightly in excess of the average. The most unseasonably warm months were February, May, October, and November, whereas only April was unseasonably cold. There were six months of temperature above the average record and six months below. The bright sunshine record showed five months in excess and seven months deficient. The sunniest month of the year was June, when the record of sunshine exceeded the average by 50 hours.

There were 18 days on which snow fell, and the total depth would probably aggregate to 2 feet; the greatest quantity of snow fell during Easter week: about 2 inches fell on Easter Sunday, April 19, about 6 inches on April 23, and about 3 inches on April 25. Such a fall of snow as that experienced during the Easter season has not occurred at Rothamsted since the year 1876. From April 11 to 14 in that year a great quantity of snow fell, which averaged more than a foot in depth, and drifts in the narrow lanes around the Rothamsted estate were from three to four feet deep.

January of 1908 gave 14 hours more than average sunshine, but both rainfall and temperature were less than the normal.

February, the "double-faced," was quite in accordance with ancient traditions. In its short space it treated us to hail, snow, frost, lightning, rain, and gales, to say nothing of the sudden transformations that occurred as regards temperature, which, on the whole, was high compared with the average, while rainfall and sunshine were deficient. The comparative genial weather of the first three weeks of February encouraged both farmers and gardeners to proceed briskly with outdoor work. Gardeners who were fortunate enough to secure a good seed bed, sowed seed of onions, parsnips, broad beans, and early peas extensively.

March was a month of "many weathers." On the first and third days of the month about 3 inches of snow fell, and the amount of water from the rain and melted snow on these days measured about 22,600 gallons per acre. The total rainfall for the whole of March was nearly 3½ inches, being 1½ inches in excess of the average. The general character of March was cold, sunless, and gloomy.

May and June each gave a deficiency of rain, with a higher than average mean temperature and bright sunshine. The three English usual harvest months of July, August, and September recorded a deficiency of rain, a lower than average temperature and of bright sunshine.

The three months of October, November, and December gave a small quantity of rain, especially November, which recorded the smallest monthly total of the whole year; less than one inch was measured, being 1¾ inch below the average of the previous 55 years. The last three months of the year were warmer than the average, more particularly October, and to a less degree November also. October and November recorded 36 hours of bright sunshine in excess of the average, while December was gloomy, and gave 14 hours of sunshine deficiency.

The yearly data shows that the twelve months recorded a total rainfall of 25¼ inches, against an average for the previous 55 years, 1853-1907, of slightly over 28 inches, being 2¾ inches deficient; it is also 2 inches less than the record of 1907. Calculating these figures up to the acre we find that during the whole year 2,556 tons of water have fallen on each acre of land, which is about 284 tons of water deficient. The total rainfall for the last four months of the year fell short of the average for the same period in the previous 55 years by 3¾ inches, which is equivalent to a loss of 76,197 gallons on each acre in the underground water supply of this district. Last year at the same time there was an excess of 60,859 gallons per acre.

The mean temperature for the whole year was 48.2 degrees, which is very little in excess of the average of the past 30 years, 1878-1907, although the three last months of the year, recorded an aggregate of 7.2 degrees higher than the normal. The bright sunshine for the year amounted to 1,638 hours, being 35 hours in excess of the average; whilst in 1907 the total sunshine was 49 hours deficient.

Under these climatic conditions the experimental hay crop at Rothamsted was under all conditions of manuring less than the average yield, ranging from 5 to 18 cwt. of hay deficient, and considerably below that of 1907. As a set off against the bulky crop of 1907, which was badly harvested, the crop of 1908 was cut and carried with very little trouble.

The produce of the experimental wheat field was somewhat variable—about one-half of the plots under different manures gave above the average yield, while the remaining half produced a slightly lower than average quantity; but the quality, as indicated by the weight per bushel, was considerably above the average record, and ranged from 63lb. to 65lb. per bushel.

The experimental barley crop was, under all conditions of manuring, except that of the farmyard manure plot, below the average in yield, and in some instances very considerably below, while the weight per bushel was higher than the average.

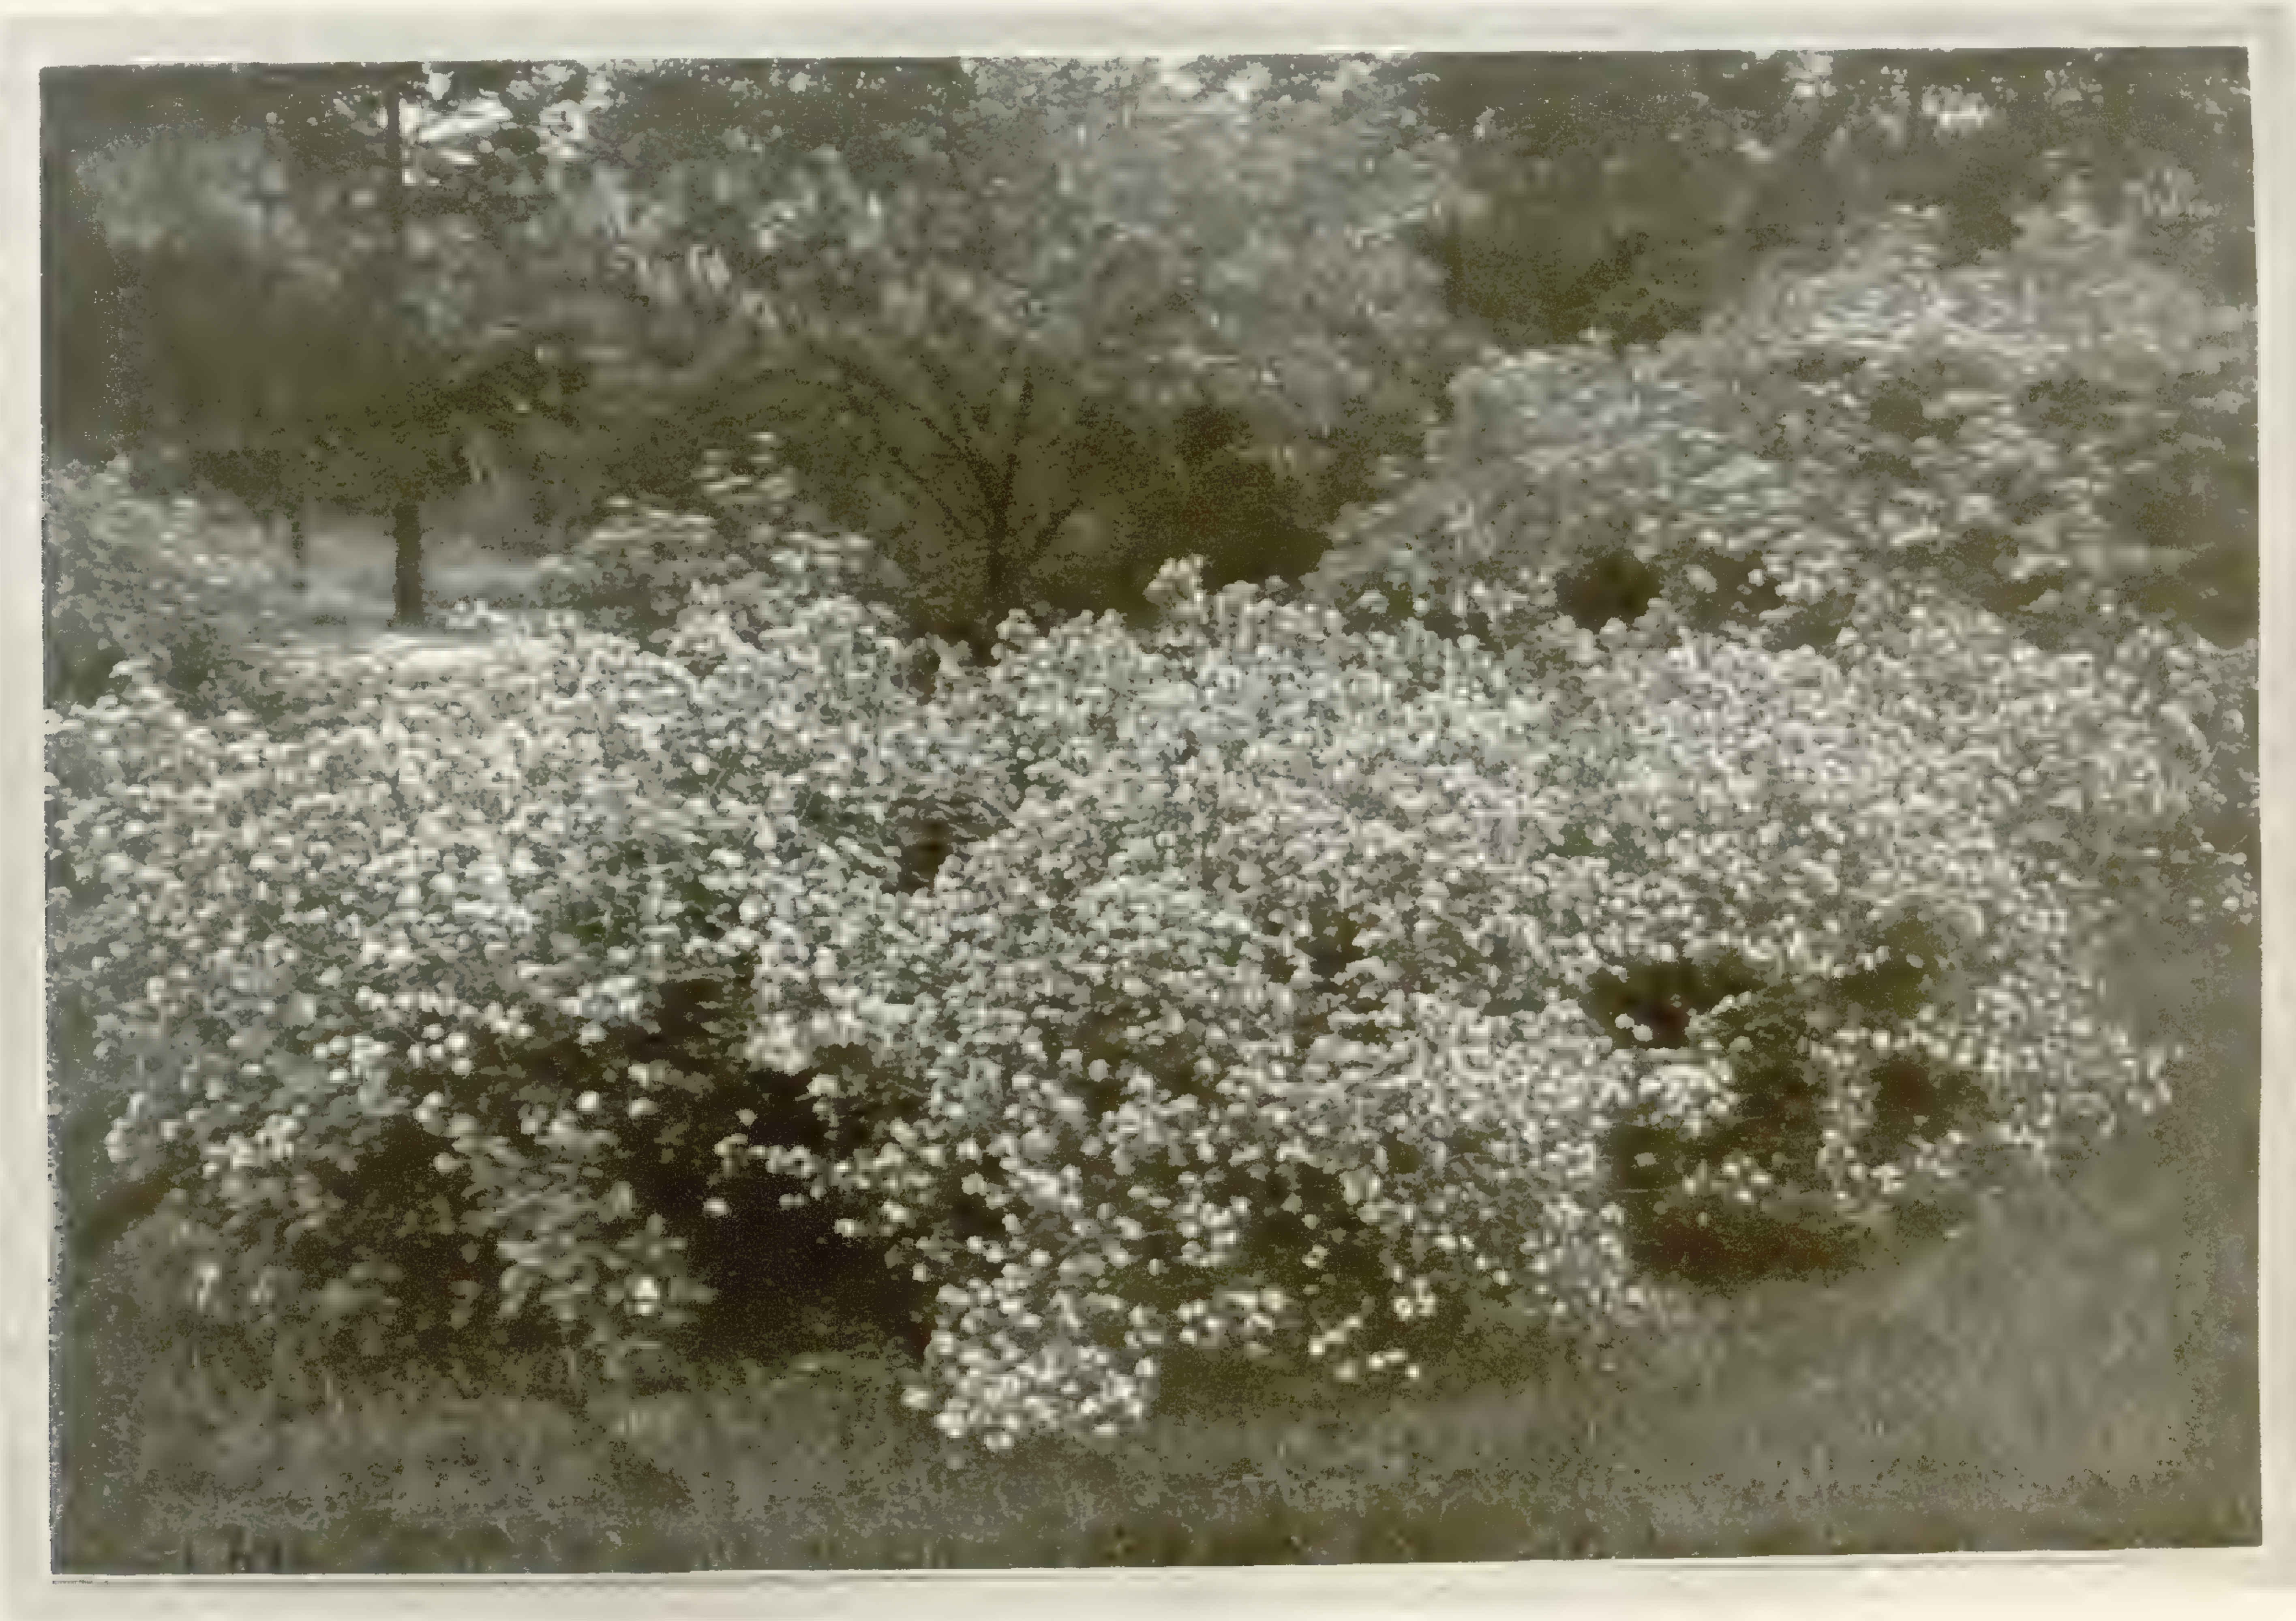
The root crops were variable, there being some good areas of mangolds and swedes, and some very bad. The general character of growth was an excessive amount of leaf, which the lateness of the season failed to ripen in sufficient time for the lifting.

Potatoes, on the whole, were a large crop, but disease set in very badly after the tubers were harvested.

Harpenden. J. J. Willis.

JAMESIA AMERICANA.

Although introduced to cultivation between forty and fifty years ago, this charming deciduous shrub is so seldom seen beyond the boundaries of botanic gardens that it appears desirable planters should have their attention drawn to its merits. Jamesia americana is not showy, and that may, perhaps, have militated against it becoming popular; but, if not showy, it is extremely beautiful, and it strongly appeals to those who appreciate elegance of growth and quiet colouring at their true value. It belongs to a monotypic genus, and is a native of the Rocky Mountains, Colorado, whence it was introduced to cultivation in 1865. The growth is light and elegant, and attains a height of between two and three feet; the leaves are oval, serrated at the edges, bright green on the upper surface, and greyish white on the undersides; the flowers are pure white, about half an inch in diameter, and borne in paniculate clusters at the points of the shoots. The habit of growth and the freedom with which the flowers are produced are so well shown in the illustration as to render other than a brief reference wholly unnecessary. The bed portrayed occupies a position in the Royal Gardens, Kew, at the southern end of the holly walk, and consequently not far distant from the Pagoda, and the photograph was taken in June.



JAMESIA AMERICANA IN THE KEW ARBORETUM.
An elegant hardy American shrub with white flowers.

It is wholly unnecessary to write at length with regard to the cultural requirements of the shrub. It is quite hardy in this country, and will thrive in any soil that is fairly friable and well drained. On cold, wet soils the wood might not become fully matured, and the flower production be less than would be the case under favourable conditions; but no plants have yet come under the notice of the writer that have failed to ripen their growths, or to produce a profusion of flowers. Propagation is readily effected by means of cuttings of well-ripened shoots. The cuttings should be taken early in the autumn, be prepared in accordance with the orthodox practice, and inserted in pots, pans, or boxes filled with sandy soil, and be placed in an unheated frame. It is necessary, as in the case of the cuttings of other shrubs, to keep the frame rather close until they have callused, when the ventilation can be gradually increased. G.

VARIETY IN THE PLANT STOVE.

Even warm greenhouses and plant stoves of great extent are often filled with only the most usual shrubs, climbers, and plants, these repeated monotonously again and again; one genista or hoya is remarkably like another, it should be remembered, and the larger conservatory subjects of this kind do not require to be massed for colour effect, as we may well group quantities of one species of perennial in the herbaceous border. I am sure gardeners, and garden owners, would derive greater satisfaction from cultivating a finer assortment of plants under glass, even if obliged, therefore, to part with numbers of the present occupants of shelves and stages. The most cursory consideration of possible plants will reveal neglected beauties.

Early-flowering blood lilies, or hæmanthus, may be obtained as bulbs, and potted in August or September in a compost of equal parts of peat, old chopped manure, loam, and sand; their vivid red, white, and orange blossoms make a fine display. Stately white pancratiums should not be omitted, their elegant growth and bloom shape, their long-lasting nature, their fragrance, alike entitle them to cultivation. No peat should be used in their compost, and they should be encouraged by bi-weekly applications of different liquid manures.

The white and palest pink paullinas are interesting and uncommon, succeeding best when their tendrils of downy, finely cut, evergreen leaves are trained up wire netting, either around pillars or against side and roof glass. They are suited by a compost of equal parts of loam and leaf-mould, with sand, but require a tempera- any time, so are only fitted for the stove.

The Chilian pitcher flower, sarmienta, may be enjoyed in a greenhouse many degrees cooler, gorgeous and tropical though its appearance is. This is a more vigorous climber, yet it is generally grown in pans or baskets, like an orchid, and allowed to drape downwards. It is easy to cultivate it in a pot on the top shelf of the staging, and persuade it to attach its creeping stems to cords stretched across the angle of the roof glass, thus making a light canopy studded by scarlet blooms. The compost used for orchid potting will suit it, and throughout summer ample watering and daily syringing will be necessary. It belongs to the Gesneraceæ.

Mahernia is worth growing, in equal parts of loam, peat, leaf-mould, and sand, and a moderate temperature, for the red and orange flowers are perfumed, and the plant can be kept in a trim, shrub-like shape.

The shady portions of the stove may be beautified by ixoras, in scarlet, orange, salmon, and white, evergreen shrubs which flourish in pots with a compost of two parts peat to one of loam, and one of coarse silver sand. After the blossoms are over, which will be by the end of October, the ixoras should be placed into a sunny position of the house.

The orange combretum is a gay stove climber, preferable to the red, or even the white variety, a rapid grower, willing to cover part of a roof, and possessed of evergreen foliage. M. H.

POPULAR WINTER-FLOWERING HEATHS.

About the middle of September a few species of greenhouse heaths are disposed of by thousands at the different trade sales that take place around London at that time. These heaths are, for the greater part, grown by those who make a speciality of their culture, and cultivate them in very large quantities. The reason of this is that heaths require special treatment, it is only those that devote their undivided attention to them that can turn out the model plants that some of our nurserymen do; and yet at so cheap a rate are they disposed of that one frequently meets with charming little specimens full of bloom exposed for sale on the costermongers' barrows in the streets of London.

These are nearly always in the regulation 48 or 5in. pots, but within the last few years quite an industry has sprung up of growing little flowering plants of some of these heaths in thumb pots. Of course, only small-growing kinds are suited for this purpose, one of the best being Erica gracilis, while Erica persoluta alba is also a favourite for this mode of culture.

Erica gracilis has been for a long time in flower, and is now past its best. It is a well-known and popular kind, and when laden with its myriads of tiny rose-purple or purplish-red blossoms, it is decidedly pretty. Some years ago a variety, alba, was distributed, but the flowers were in colour a long way removed from white, and it never became popular. More recently the variety nivalis was put into commerce, and the first year the blossoms appeared whiter than I have seen them since. Though decidedly flushed with pink the flowers of this afford a pleasing variety from those of the normal form. Of what is regarded as the typical kind there is a considerable amount of variation in the colour of the flowers, some cultivators turning out plants whose blossoms are of a richer tint than others. In some cases this has been attributed to the superiority of the particular form or variety, but it is in many instances due to the treatment the plants have received. Exposure to air and sunshine naturally deepens the colour of the flowers, hence, to ensure the whitest flowers of the variety nivalis, they are allowed to develop in a partially shaded position.

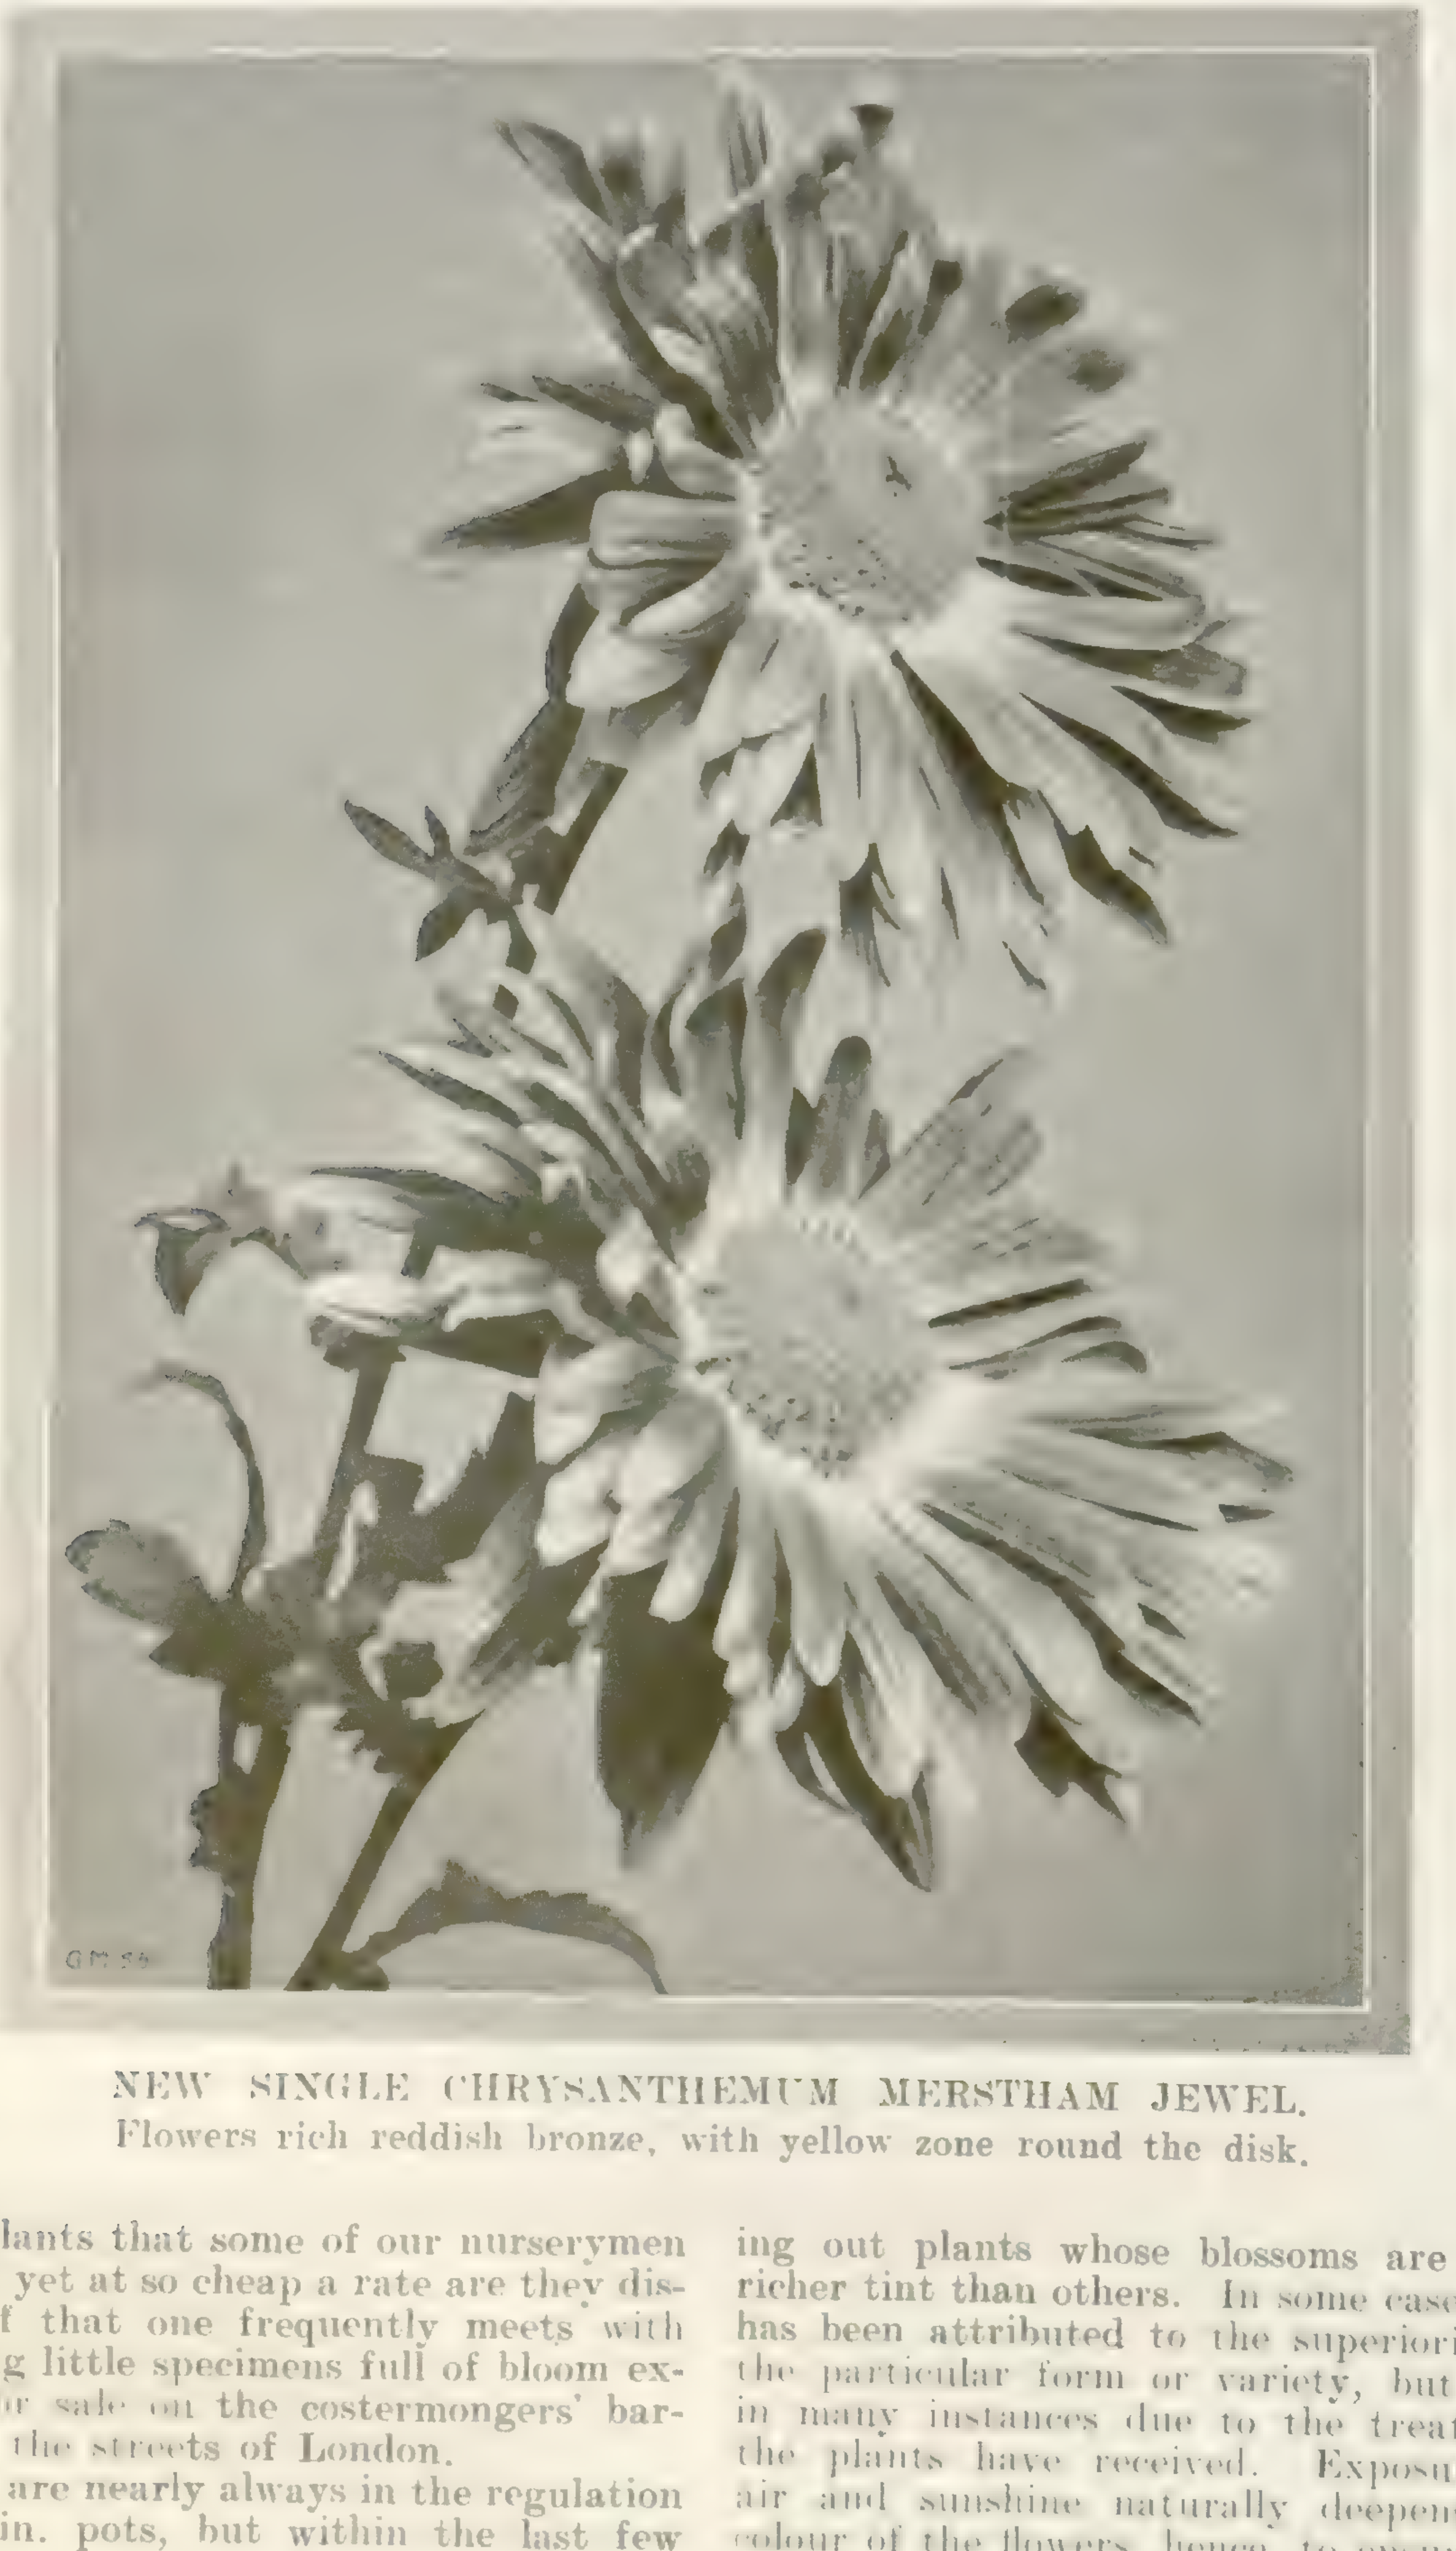
A good companion plant to Erica gracilis, but of a somewhat lower and rather more spreading habit of growth is Erica caffra, which, like the species previously mentioned, was introduced from South Africa over a century ago. It is not so much grown as it was, but being of comparatively easy culture, very floriferous, and blooming during the dull autumnal period it is especially welcome.

Erica hyemalis stands out as one of the most popular of all greenhouse heaths, and deservedly so, for when at its best it is remarkably showy, and good examples always sell well. The fact of its being at its best during the winter months is a great point in its favour, and immense numbers of flowering plants are disposed of during the Christmas season. As with Erica gracilis some cultivators obtain flowers of a richer colour than others. This has led to the plants being at times regarded as distinct varieties, but this variation is now generally looked upon as caused by details of culture. There is one well-marked variety with pure white blossoms which afford a very pleasing change from those of the normal form. It is equally vigorous in growth and flowering examples can be purchased at about the same rate as the other. Strange as it may appear in the case of so popular a member of the heath family, there is, I believe, no record of the early history of Erica hyemalis, though it has been largely grown for the last fifty years or more. It is generally considered to be of garden origin, and the South African Erica Linnæana is by some looked upon as a probable parent. The white variety, alba, has also been grown for years, as it was given a first class certificate by the Royal Horticultural Society as long ago as January 10, 1882.

Another good heath is Erica melanthera, in which the blossoms are pinkish mauve, an uncommon tint. The specific name is derived from the blackish-coloured anthers which stand out very conspicuously against the lighter tinted background. It is of comparatively easy culture, and well-flowered examples are very pretty. A notable feature of this heath is the somewhat faint yet pleasing perfume of the blossoms.

While the above constitute what may be regarded as winter-flowering heaths, yet with the advent of the new year other kinds come in, and one of the most popular of these is Erica Wilmoreana, which, like E. hyemalis, is of garden origin.

W. T.



NEW SINGLE CHRYSANTHEMUM MERSTHAM JEWEL.
Flowers rich reddish bronze, with yellow zone round the disk.

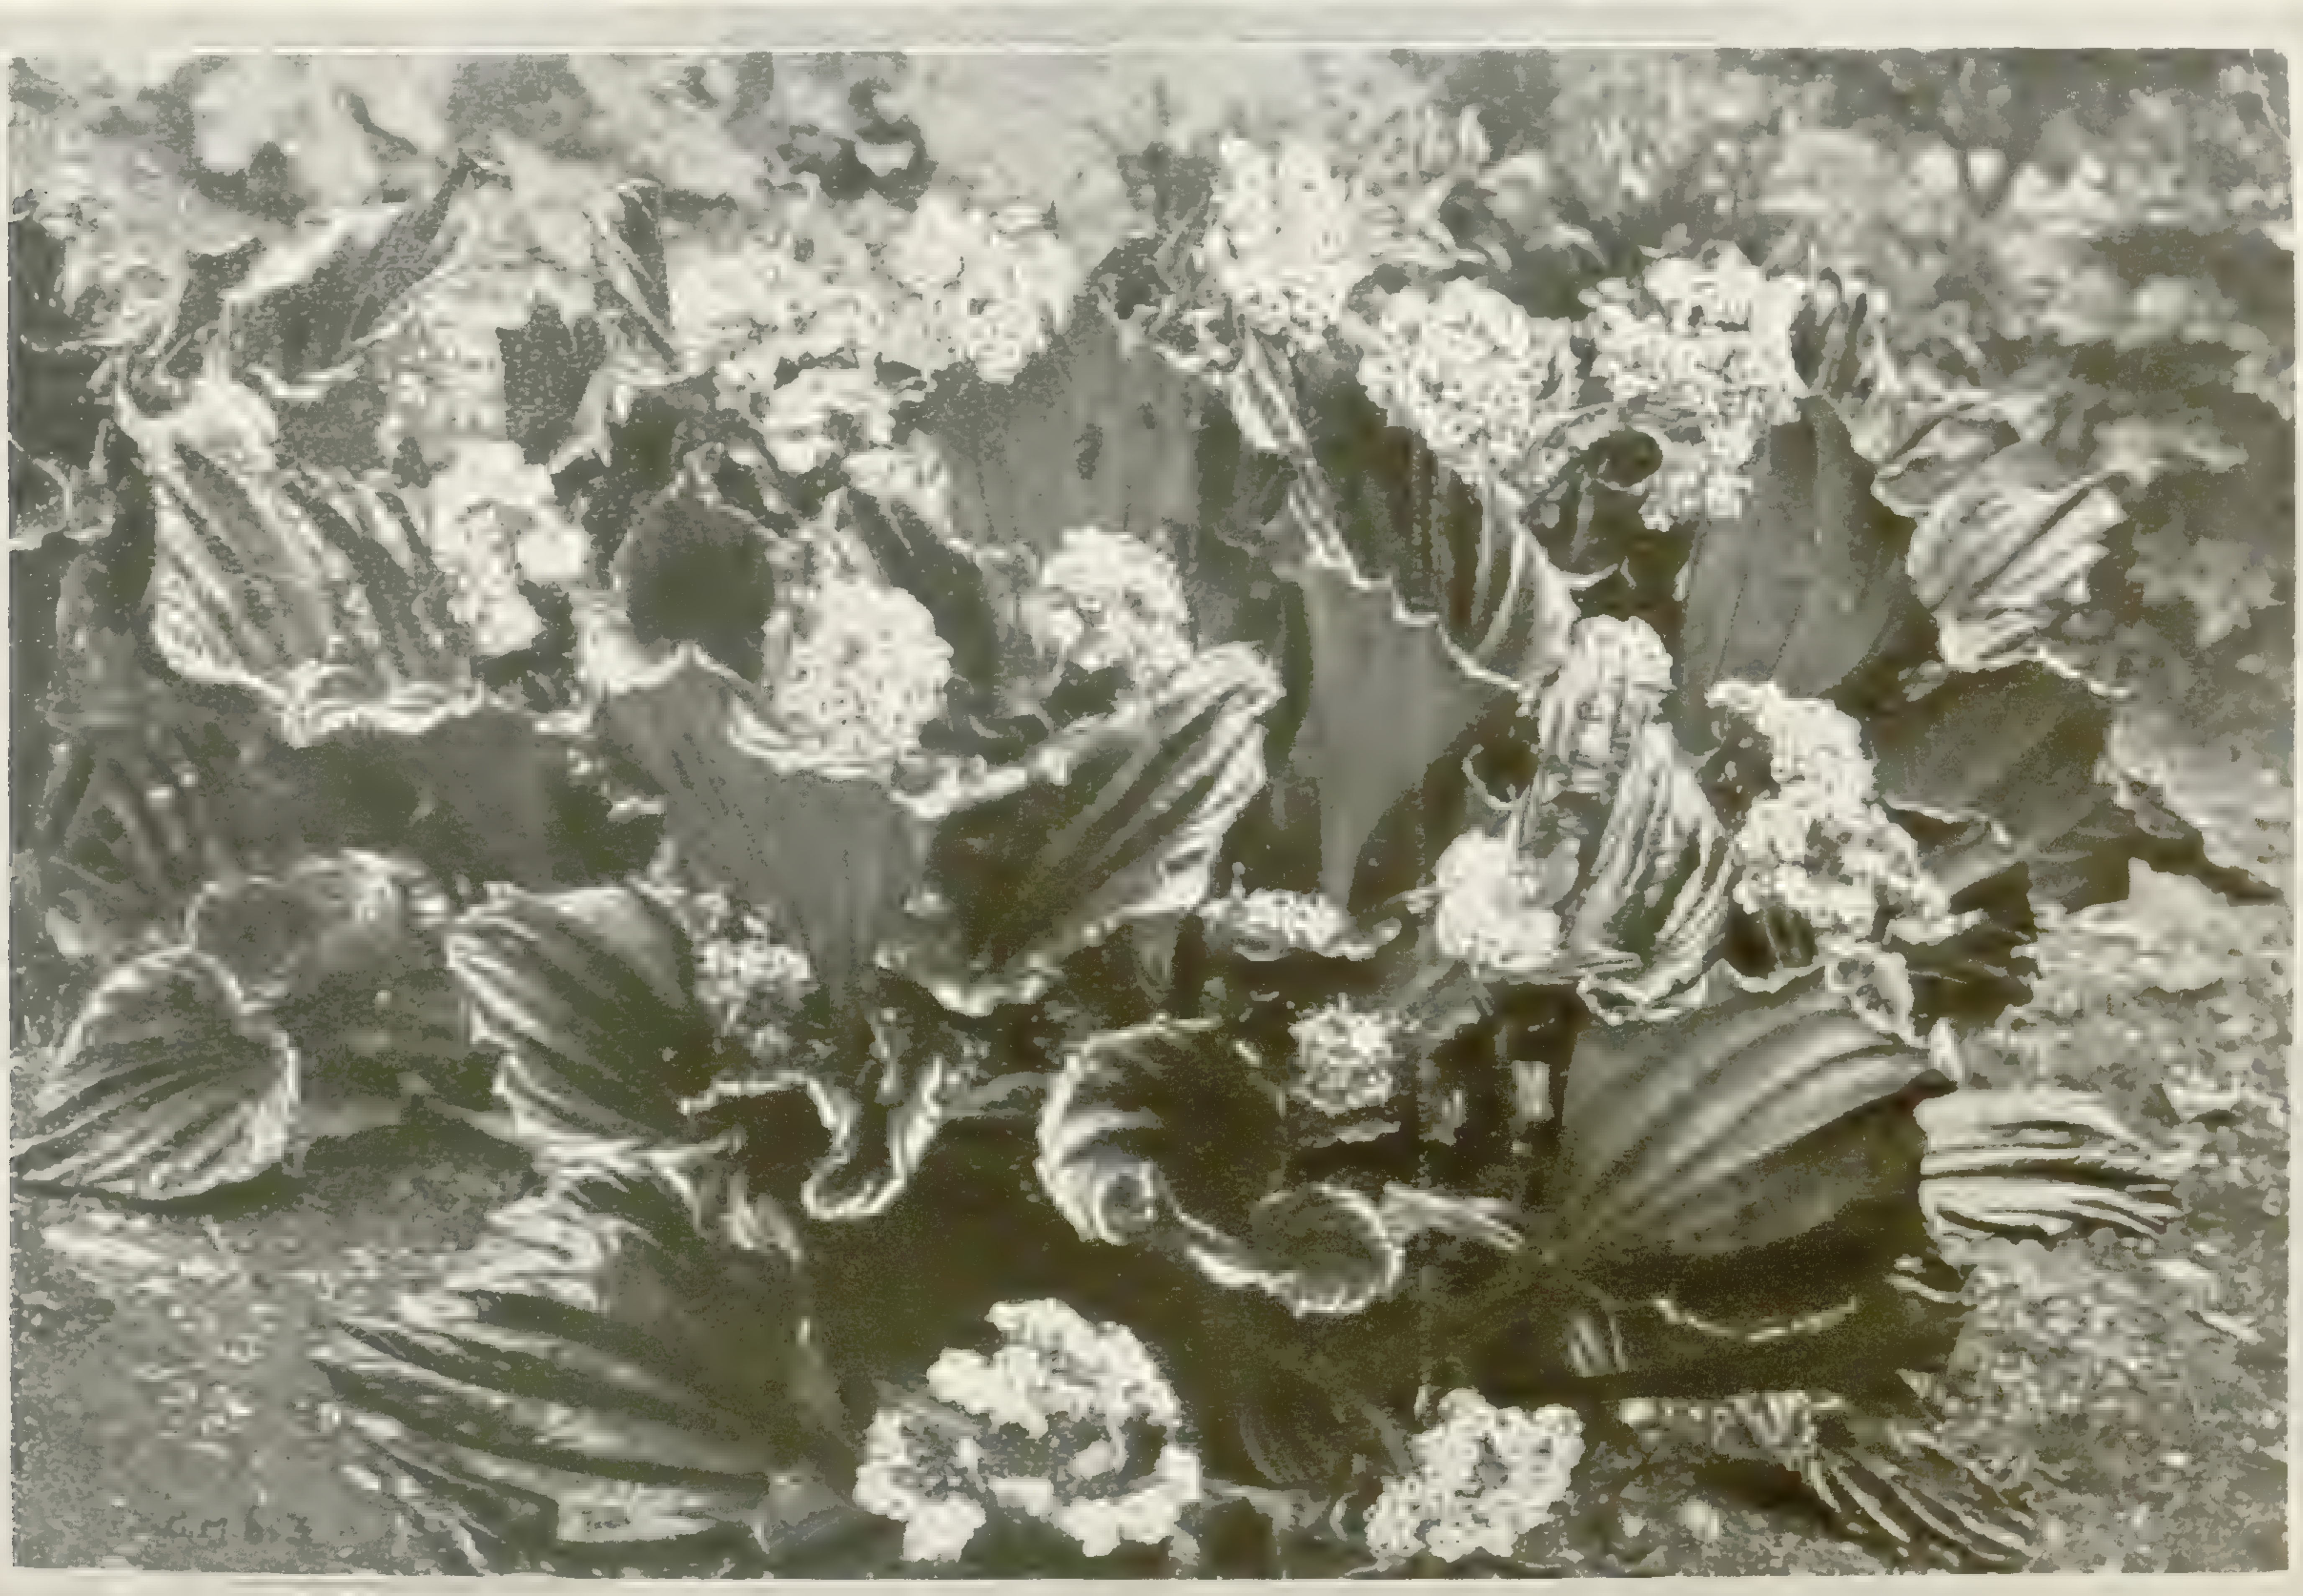
SINGLE CHRYSANTHEMUM MERSTHAM JEWEL.

Numerous new single chrysanthemums were placed before the flower-loving public during the autumn of 1908, and a considerable number secured recognition at the hands of the leading societies. Even among these latter there were several that did not meet with general approval, for, after all, so much depends upon the point of view. One variety, however, that did seem to please the great majority of chrysanthemum enthusiasts was the handsome Merstham Jewel, figured in the present issue. When disbudded this has very fine flowers, and when undisbudded the blooms are produced in beautiful sprays. Merstham Jewel continues to bloom over a long period, commencing in October and continuing well into December. Its colouring, rich reddish-bronze, with yellow zone round the disk, renders the flowers very effective. There is not the slightest doubt as to the popularity this variety will enjoy when it is distributed, for it is one of the best of many fine single varieties raised and sent out by Messrs. W. Wells and Co., Merstham. The variety has received the First Class Certificate of the National Chrysanthemum Society, and the Award of Merit of the Royal Horticultural Society.

MYOSOTIDIUM NOBILE.

The New Zealand forget-me-not, as it is called, is a native of Chatham Island. It was introduced in 1858, and was first described in the "Botanical Magazine" in 1859, but for many years was treated solely as a greenhouse plant, and the earlier illustrations of it were evidently prepared from poor specimens which had been grown under glass.

Mr. John D. Enys, of Enys, in Cornwall, whose charming garden has been well illustrated in these pages, was the first to bring seeds of the myosotidium from the Antipodes to that county, and to start its culture as an open-air plant. He distributed seed among his neighbours, and there are but few gardens in Cornwall at the present day where the plant is not grown. There is certainly no comparison between the relatively weak growth exhibited by pot plants and the robust vigour manifested by well-grown specimens in the open garden; these plants sometimes attain a height of three feet, and carry great glossy-green leaves suggestive of rhubarb. Leaves have been known to grow to a length of two feet and a breadth of eighteen inches. These splendid Cornish examples throw up numbers of branching bloom sprays, the flower heads measuring six inches or more in diameter, while the individual blossoms are about half an inch across. In the colour of the flowers there is considerable variation. In the best form they are of a uniform deep blue, but in others they are rich blue in the centre, fading to almost white at the edge of the flower. At Enys a pure white variety is also grown.



A FINELY-FLOWERED SPECIMEN OF MYOSOTIDIUM NOBILE IN A SOUTH DEVON GARDEN.

The leaves are bright glossy green, and the flowers light blue.

In its native island the myosotidium grows on the sea beach just above high-water mark, in the sand of the shore, where it must often be sprinkled with the wind-borne spray. There is at Enys a painting of the myosotidium growing in its native habitat, and fringing the beach at Chatham Island with a long line of deep blue. Unfortunately, according to Mr. Enys, the plant is now being rapidly exterminated by cattle and other agencies. The fact that in its home the plant grows in sea sand has led to the employment of this in a greater or lesser degree in preparing the ground for its reception. In some cases only a heavy mulch of sea sand is given over a compost of porous soil, but at Menabilly, where a large number of plants of myosotidium are present, that are unusually fine, they are grown entirely in sea sand. Large holes are dug out, a cart is sent down to the beach and filled with sand, and this is emptied into the holes, and the seedlings planted in it. At Menabilly the plants are grown immediately in front of high walls with varying exposures, but are not found to do so well where the wall faces due south as in sites not so exposed to the sun.

Mr. Enys used formerly to grow his plants under a wall facing south-west, but he has now made a plantation under a north wall, which has shown good growth, and flowered well last season. In 1907 Mr. Enys, at considerable trouble and expense, sent three large plants in full bloom, in tubs, to the Temple Show, where they created widespread interest among the visitors, who had never seen the plant before. The myosotidium seeds freely, and in some gardens the self-sown seedlings may be seen springing up in large numbers around the parent. Plants flower in three years from seed sowing, but deteriorate after a few years' flowering, and, when loss of vigour is apparent, they are removed, and seedlings planted in their place.

When in full growth the myosotidium is partial to an abundant water supply. The plants are generally in the zenith of their beauty in the month of May, when a large colony, carrying hundreds of great deep blue flower heads, is a wondrous sight. It is, unfortunately, only in the south-west that this plant can be treated as an open-air subject.

The accompanying illustration shows a plant growing in a South Devon garden close to the mouth of the river Dart. It is planted in a depth of three feet of sand obtained from the tidal portion of that river, which is, therefore, practically, sea sand. It was two feet six inches in height, and about three feet in breadth, while it carried over twenty flower heads, some of which were eight inches across.

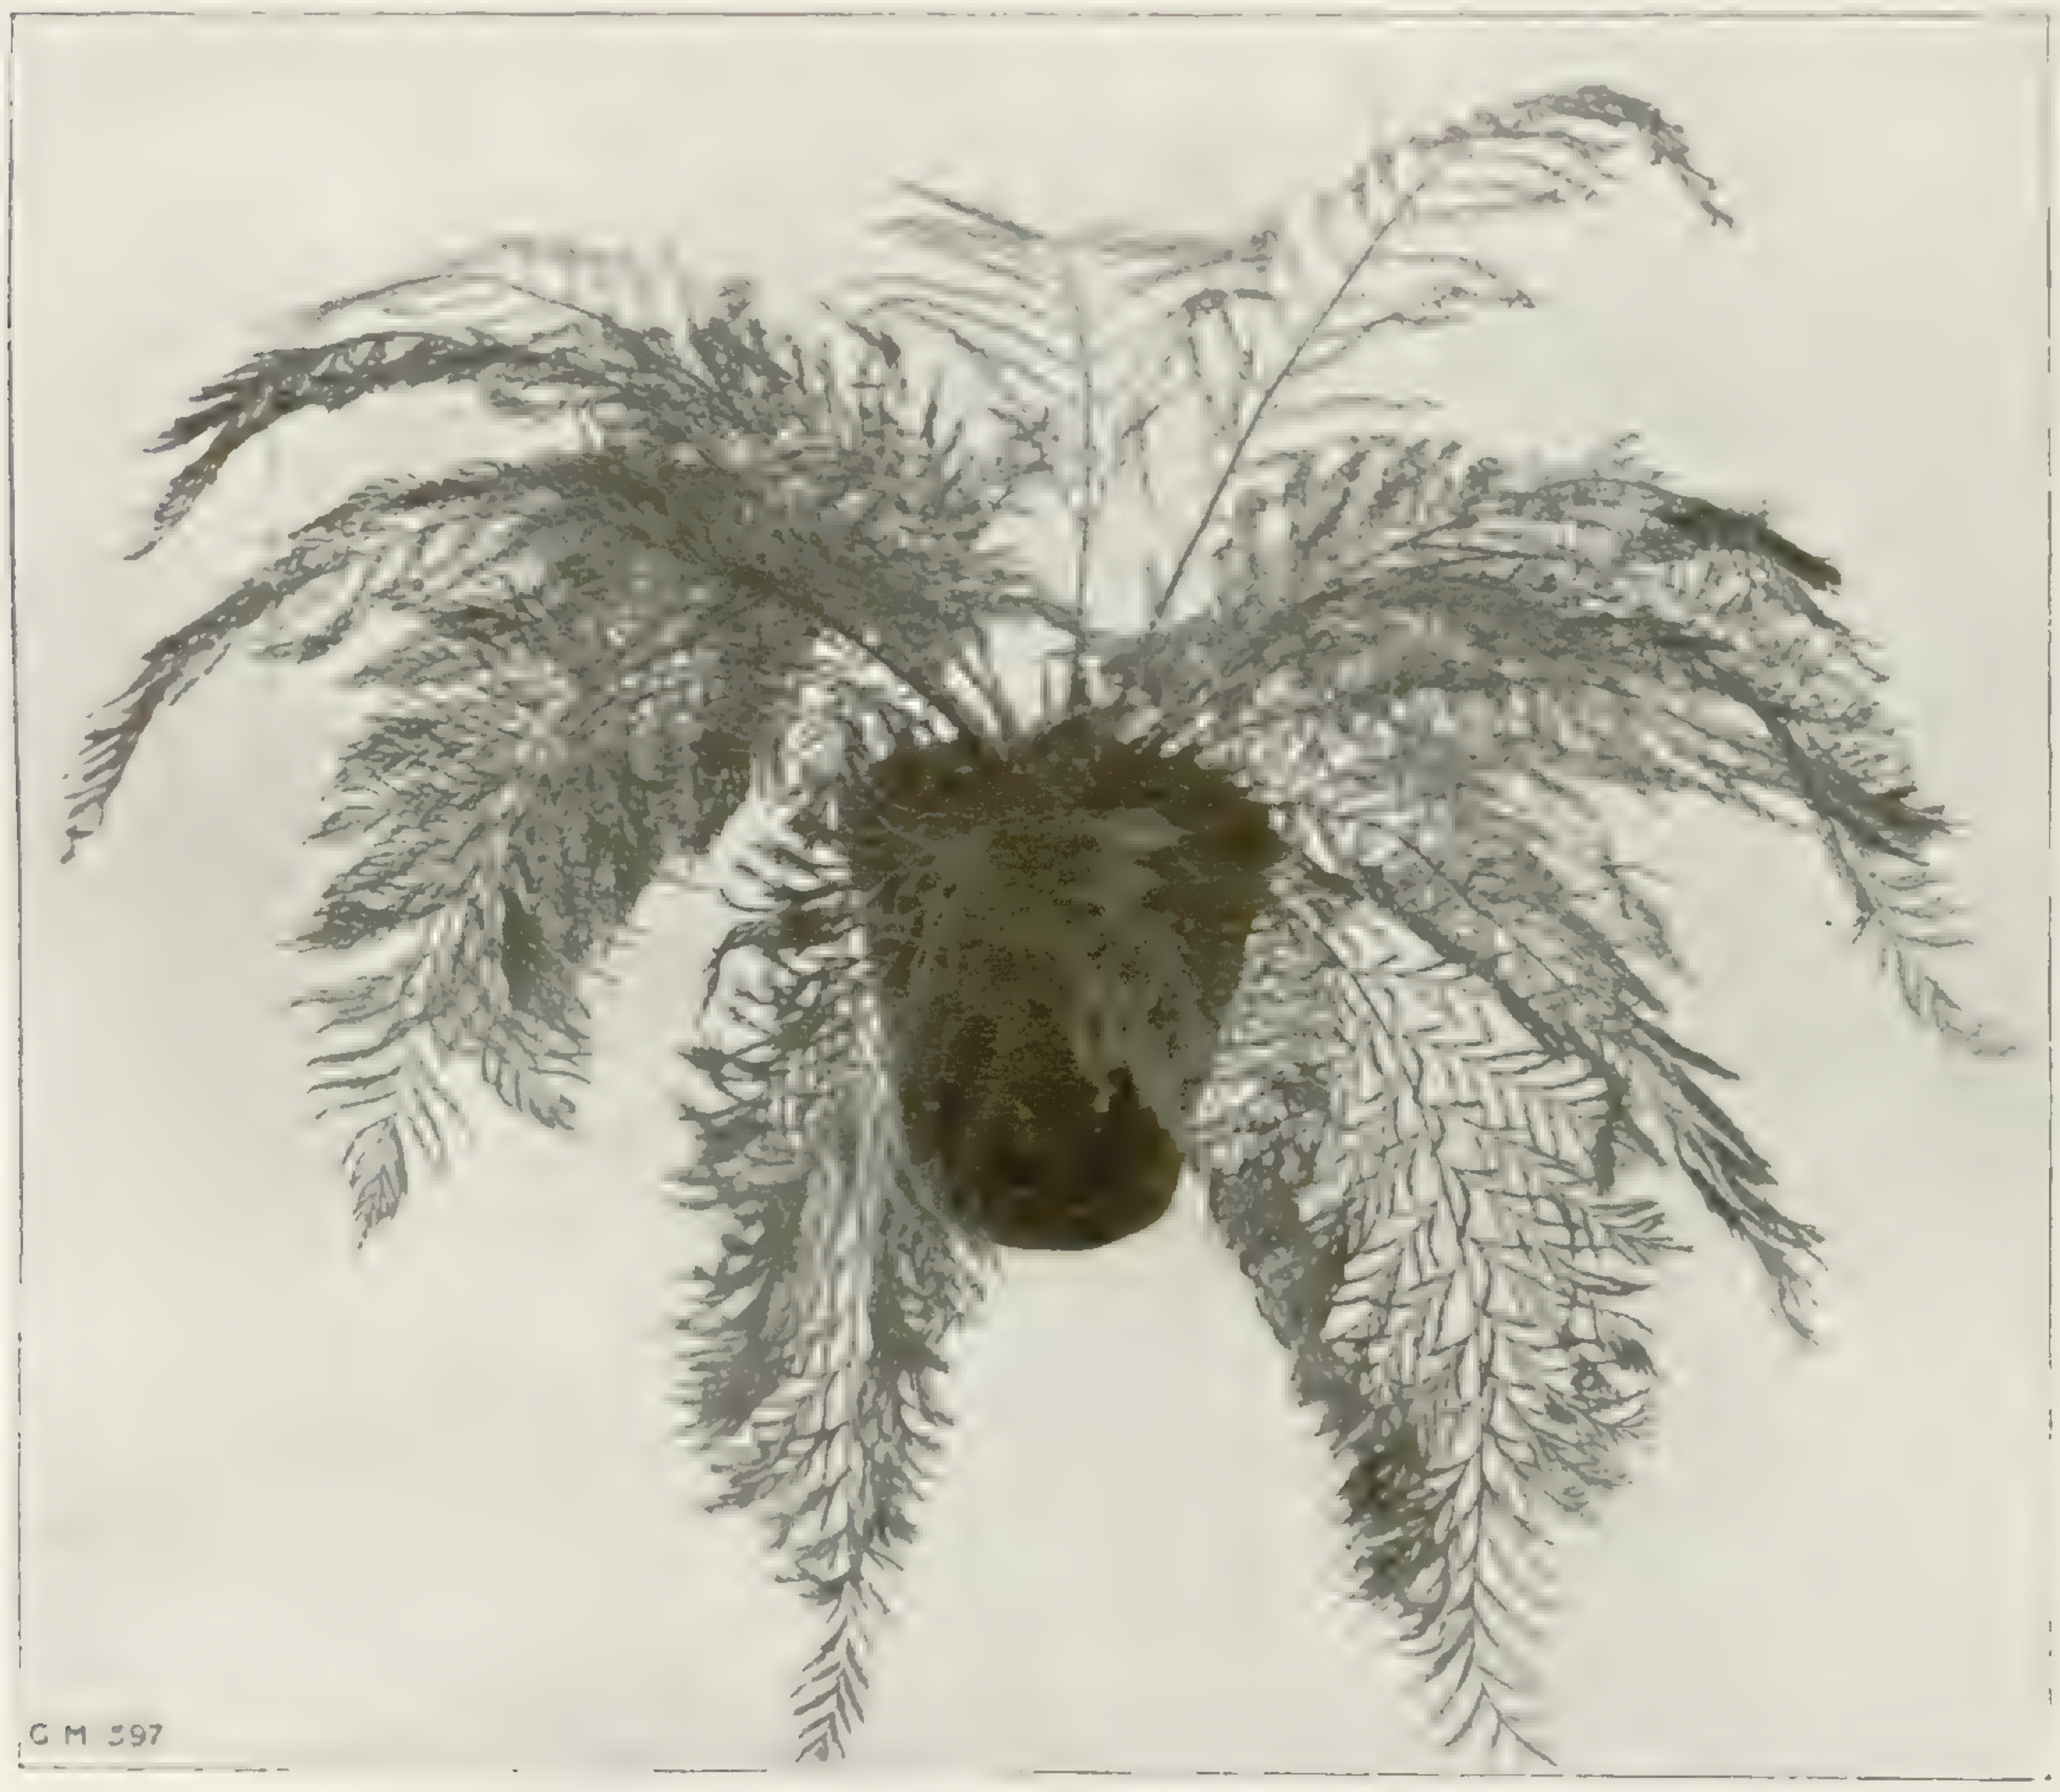
S. W. Fitzherbert.

PEARS IN WINTER.

Admitting everything which can be advanced in praise of apples, there is no gainsaying the fact that pears, and especially when of full average flavour, have a great value in winter time when the range of dessert fruit is so limited. Unfortunately, when the new year has extended but a short length, the supply of pears becomes extremely small; indeed, unless special precaution is taken in their gathering, and there is suitable storing convenience, there is sometimes a dearth, even on New Year's Day. There are a few varieties that are credited with a season extending from January to March or April, but our experience of March pears is by no means assuring. Much, however, depends on the soil in which trees are grown, and the convenience of the fruit room. Here these tend towards an early closing season.

With us the latest to supply the dessert and the most regular in bearing is Ne Plus Meuris. It cannot claim high merit in the matter of flavour, but the palate is scarcely so critical in January as it is in November, when there are so many good pears available. Bergamotte d'Esperen belongs to the higher flavoured section, and the fruit continues sound and of good quality into February. Grown in cordon form, and well attended to at the roots, this esteemed winter variety will attain to a good size and maintain a sound skin and flesh. In the open, except in favourable districts, such late varieties are not always a success. They require the influence of a sheltering wall to do them justice, and well they deserve it. Another variety which presumably has a useful future before it for late use is the Blickling, certificated in mid-January by the Fruit Committee of the R.H.S. Easter Beurre generally belies its name, for we have not as yet obtained edible fruit so late as Easter, and even if we had succeeded there is, in our opinion, such an insipid thinness of flesh and flavour that our estimate of the pear is a decidedly low one. Josephine de Malines is a much better pear. This again is credited with a long season not often realised. It is useful whenever it may ripen, the only fault we have to find is that it crops lightly, at least we find it so on walls, espaliers and as a bush in the open. President Barabe is a good thick-skinned late keeping pear, that should have every encouragement. Le Lectier, again, under skilful treatment, rewards its owner with luscious and handsome fruit for the winter season. This, like Josephine de Malines, gives us a light crop, but as yet trees of this new variety are not fully established, so that we hope it may be more productive in later years. Glou Morceau has a delicate constitution and needs careful nursing in order to obtain full-grown specimens and heavy crops. It may do better on some land, certainly our light soil does not seem its ideal. Nouvelle Fulvie has come into much favour, for, though it has no external beauty, it keeps late, and has a finely-grained sweet flesh. Beurre Perran and Beurre Dubuisson are others which are destined to good service in the new year. Beurre Rance and Chaumontel need a passing mention, but are not wholly dependable. Marie Benoist on a wall grows to a large size, and keeps late. W. Strugnell.

Rood Ashton Gardens.



POLYSTICHUM ACULEATUM PULCHERRIMUM DRUERYI.

SEA LAVENDERS.

There are among the Statices, or Sea Lavenders, many very good plants from almost every point of view, such as beauty of habit and of flower, hardiness, and ease of cultivation. All are not alike in these respects, however, and not only is it desirable to discuss their relative hardiness, but also to remark upon their variations in beauty. We do not find in the species which are hardy in our climate any with the magnificent beauty of some of the tender Sea Lavenders, nor even the variety afforded by the annuals; but we do find among them flowers of great beauty, indeed, and flowers which are not only ornamental for the garden, but useful to dry for winter decorations. Of those in commerce there are nine or ten which deserve our attention and should have some consideration, and these are so different in their sizes and aspects that a few notes of description will be of service to those who think of growing some of these pretty statices, either in the border or in the rock garden. Taking them in alphabetical order we first come to Statice bellidifolia, a very neat and pleasing little plant, the appearance of whose foliage is well described by the specific name of bellidifolia or daisy-leaved. It is of much the same form as that of the daisy, but is smoother and rather larger than that of our little wilding. The flowers, which are on a small raceme, are, like those of the statices as a whole, individually small, but the effect of the number of little blue blossoms developed together makes this a pleasing little plant for the rockery or the front of the border. As it is only about six inches high, the former is the best place for its accommodation. Following this we may refer to

Statice caspica, a new species not as yet well proved in gardens, but which will likely be hardy except in places where the winters are wet. It, also, is only about six inches high, and its blue flowers, raised on little slender stems above the rather spathulate leaves, make it a pretty rock garden plant.

Statice eximea has not proved so hardy with me as I should desire, but in warm districts it should be grown either on the rockery or near the front of the border in warm, dry soils. It is about nine inches high, and has flowers which may be described as of a warm pink.

Statice Gmelini.—This may be classed as among the few hardy species which are good border plants, although not nearly so plentiful as its rival in this respect, S. latifolia. It is about the same height, reaching to some two-and-a-half feet, and giving numbers of blue flowers, lighter than those of S. latifolia, in good racemes. It is a little brittle, and in exposed places it is well to tie the stems to sticks lest they be broken off by the wind.

Statice incana.—"Pretty" may be the term applied to S. incana, as, although it is so, there are others with more pretensions to beauty. It grows fully nine inches high, and has heads made up of many flowers which are pink and white. An easy one to grow in light soils, S. incana, like others of the race, dislikes much moisture at the roots or above.

Statice latifolia is always, and justly, considered one of our best border plants, while its value for cutting is generally recognised. It often figures in show stands, and is therefore of some account when well grown. Its nominal height is two feet and a-half, but it varies a little according to soil. With large, broad leaves, and fine racemes of deep blue flowers, it is one of the most ornamental border flowers we can have. It can stand a stronger soil than the majority, and is in such correspondingly vigorous.

Statice Limonium.—This, the common Sea Lavender, is not so plentiful in a wild state in these islands as to deserve exclusion from the garden. It has rather dense heads of bluish-purple flowers. There is also a white variety, but I do not recollect having met with this in cultivation. A good species, it grows about a foot and a-half high.

Statice minuta either varies or is wrongly described or misnamed in gardens. It is said to be pale red, but, as I know it, S. minuta has bluish flowers. I have know it for a good many years, and have had it in cultivation in my garden, and I have never come across any variety with red flowers. It is a dainty little rockwork plant, only three or four inches high, and a pretty little thing indeed.

Statice speciosa.—This is said by some to be hardy, but my short experience of the plant goes to confirm the statements of the works of reference—that it is half-hardy only. As it will, however, live in certain favoured parts of England and Ireland, may be mentioned, especially as it is commerce, and as its pretty, close hea of white flowers are distinct in their from most of the other flowers of the given by outdoor perennials.

Statice tartarica.—The last I shall name at present is one whose pink flowers render it acceptable to the grower. It is also of moderate growth, and does not always attain to the height of a foot and a-half, that given in the books. There are species with finer individual flowers, but it is one which is good enough for any border or large rockery.

Cultivation.—These Sea Lavenders like, as a rule, rather good, but light soil, and in the moister parts of the country they require a lighter soil than in drier places. They are propagated by seeds or division, the former being an excellent way of raising a stock, although the number of infertile seeds is large. S. Arnott

REMARKABLE SHIELD FERNS

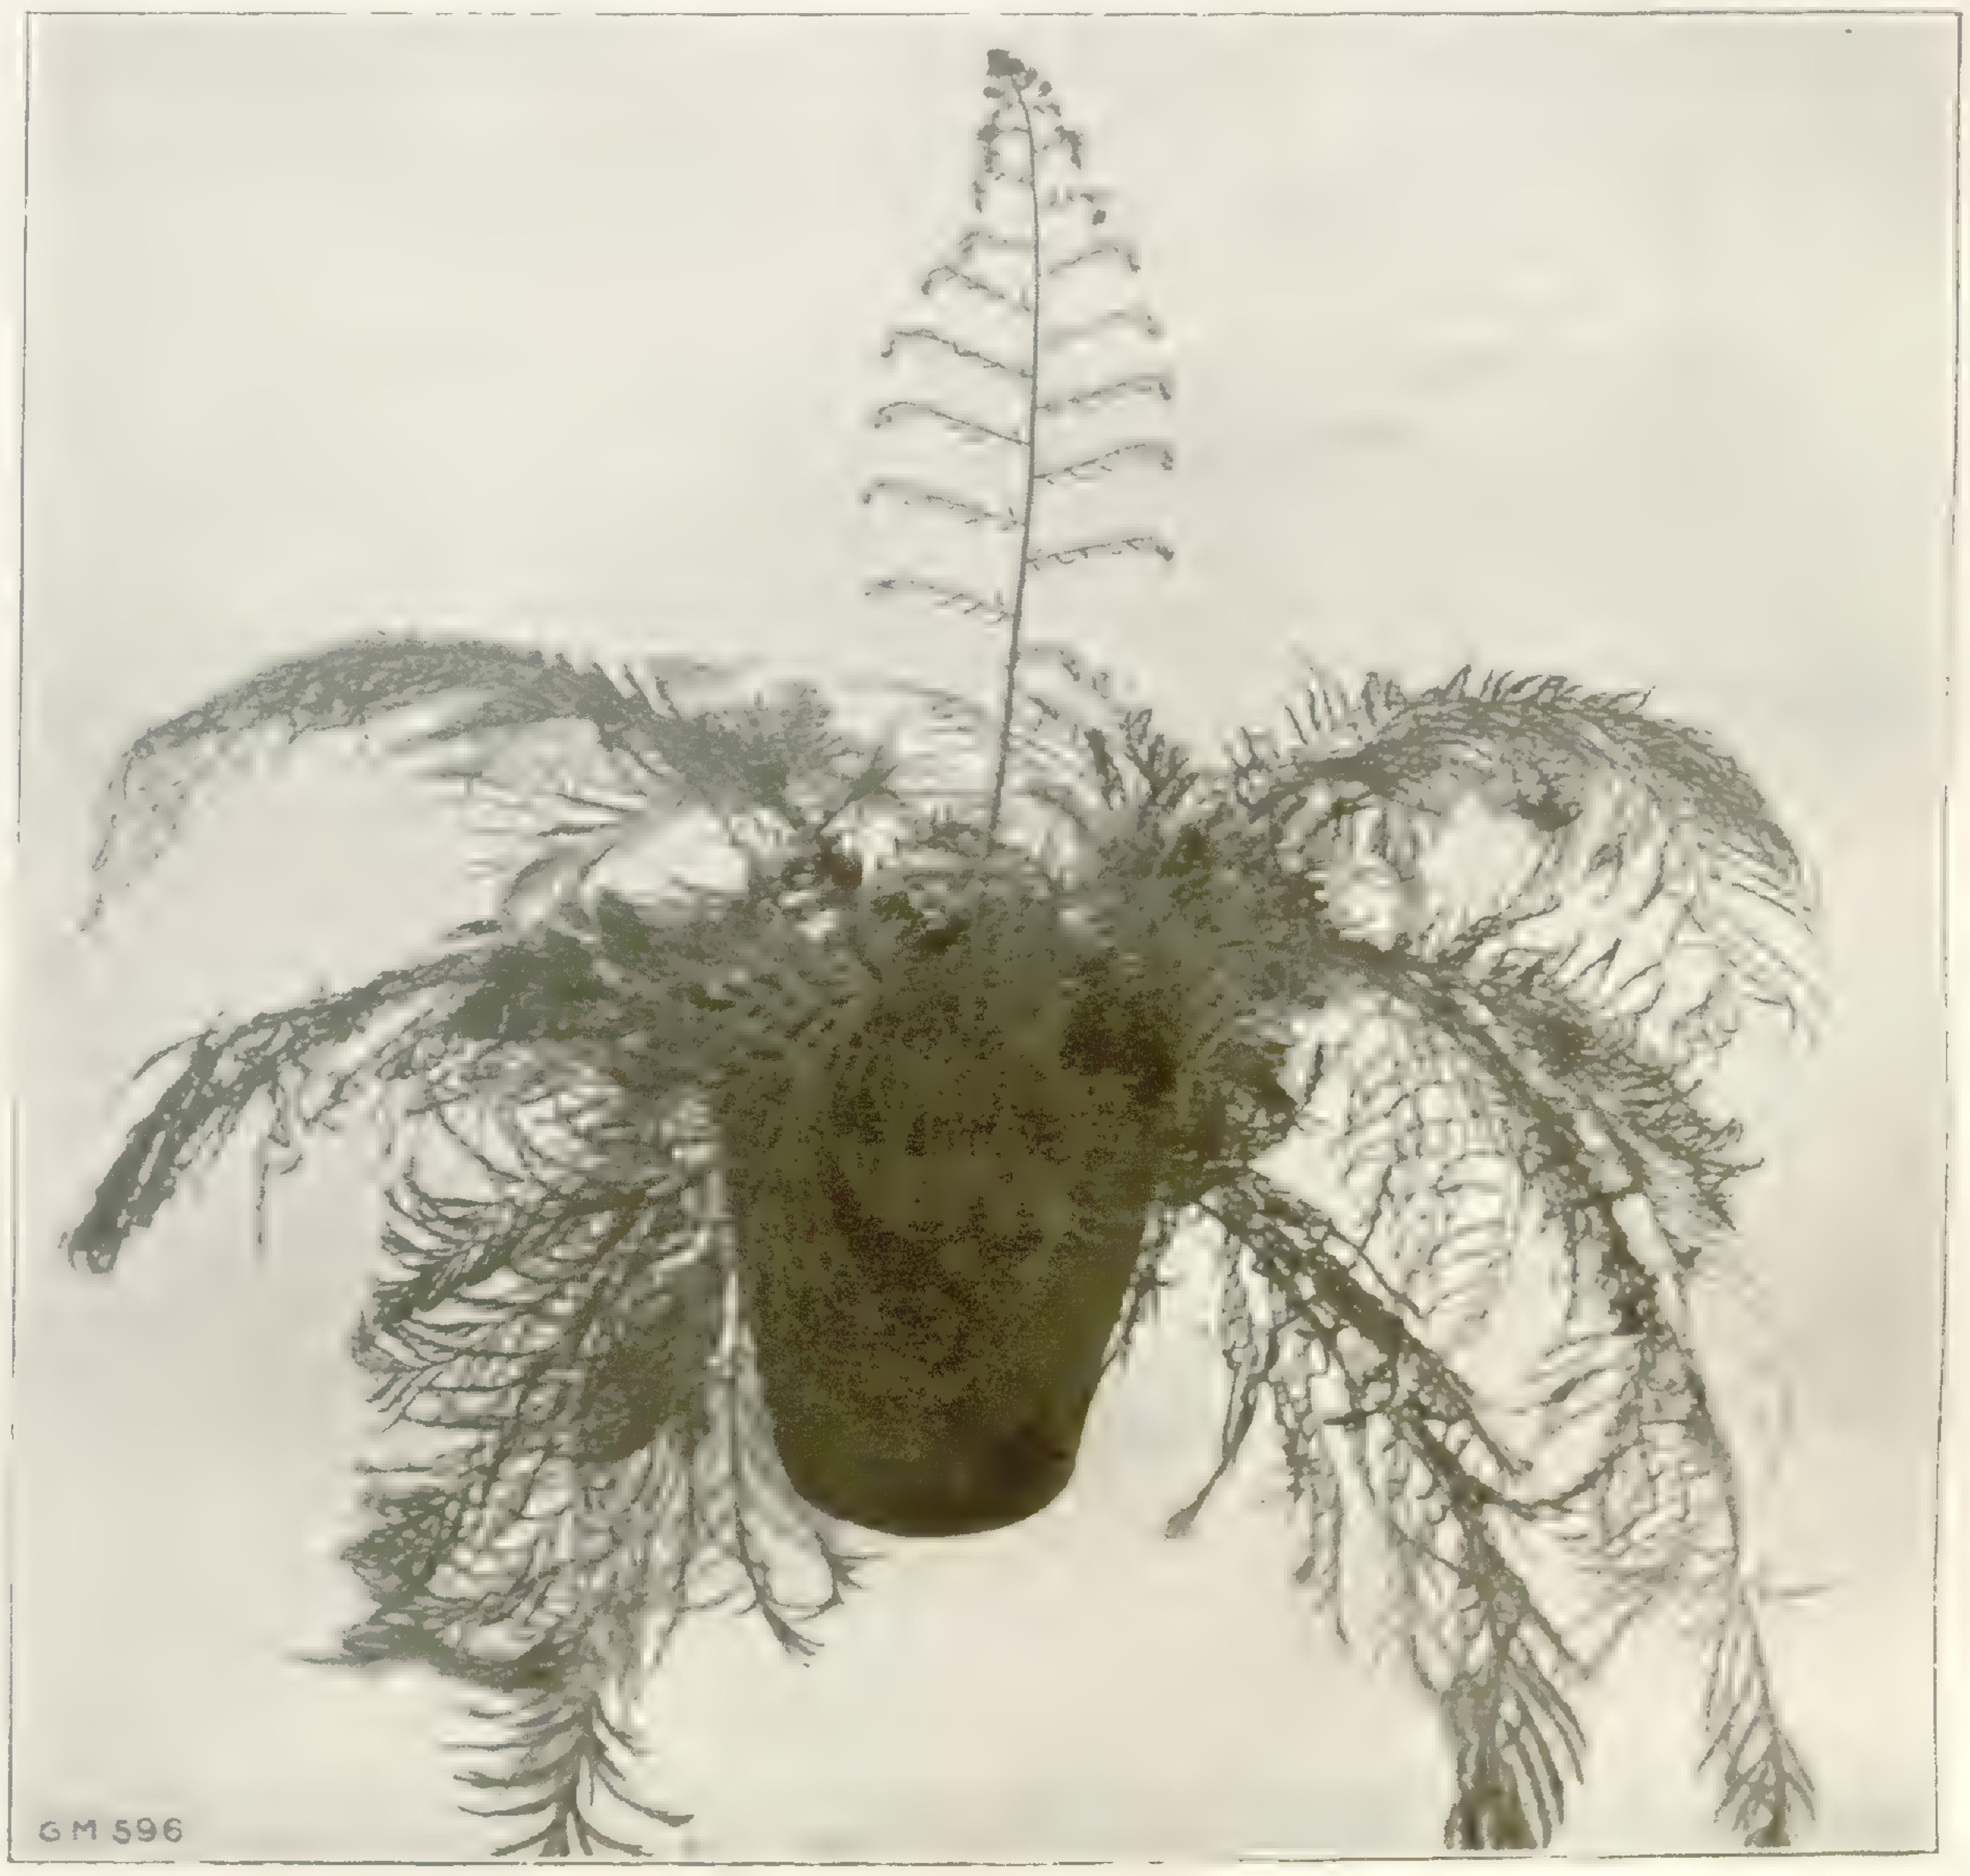
The Shield ferns, or Polystichums, of which there are three species indigenous to Great Britain, have yielded a very large number of wild sports, some of great beauty and others simply curious. By selective cultivation through the spores the typical forms of variation have, in some cases, been greatly enhanced, especially the decomposite or extra-divided section, the result being a number of most charmingly dense and mossy fronded ferns, which rival even Todea superba, the New Zealand Ostrich fern, in delicate dissection and exuberant growth. It is a curious fact that some of the best of these arose from spores of a merely tripinnate find of no marked promise, and thus gave the raisers, Colonel Jones and Dr. Fox, a very great and pleasant surprise, a batch of plumy gems arising from the first sowing.

A similarly unexpected and gratifying instance of very marked advance in fern seedlings it is the object of this note to chronicle, especially as, in some respects, the case is unique. The accompanying illustrations represent two sister plants; that is, two plants arising from the same sowing and from the same parent. One is named Polystichum aculeatum plucherrimum Drueryi, and is distinguished by a most extraordinary attenuation and lengthening of the sub-divisions, which, in many cases, are six times as long as those of the parental form, imparting a peculiarly graceful aspect and habit to the fern. This plant, it will be seen, completes its growth by further sub-division near the tips, giving a fringe-like appearance. This fern was recently awarded a first class certificate by the Royal Horticultural Society. Subsequently, another seedling of the same batch went a decided step further as regards fineness of cutting, and this is seen in P. ac. gracillimum Drueryi, while several others of the same batch of seedlings are on very similar lines.

One peculiarity in this case is that the parent plant had been reputedly barren for nearly forty years, since it was first discovered in Dorset. It is a beautifully made variety, particularly characterised by an inward overlapping of the side divisions near the slender, tapering frond tip, which gives a faint indication of the gracile character developed so largely in some of its offspring. Although of robust habit, it appeared incapable of producing spores, but being liberal in lateral offsets, it had become widely distributed in collections worthy of the name. The writer was given an offset many years ago by Mr. S. B. Wollaston, of Chiselhurst, one of our pioneers in the British fern cult, and some years since gave in his turn an offset to his neighbour, Mr. C. B. Green, who treated it so well that it grew to an immense size, and four or five years ago yielded a few spores, distributed in isolated capsules, and only distinguishable as such by a lens. These, however, were sufficient to yield in Mr. Green's hands and the writer's something like a hundred plants, which, in their infant stage, were hailed with satisfaction as forming a stock of the still rare variety. As these developed, however, in both batches, extra slender fronds began to appear, and these being separated, the result was at least a score of new varieties of the charming type figured, the beauty of which increases more and more as the plants increase in size.

The rest of the batch were mostly exact replicas of the parent form, but amongst these were two or three almost identical, not with P. aculeatum at all, but with normal P. angulare, the soft Shield fern, a distinct, but closely allied species. The advent of these beautiful varieties starts a new section, but whether it will permit of further development by bearing spores in its turn is a little doubtful, as fronds of this attenuate type are generally barren.

Chas. T. Druery, V.M.H., F.L.S.



GM 596

POLYSTICHUM ACULEATUM GRACILLIMUM DRUERYI.

WINTER-FLOWERING CARNATIONS.

A great fillip has been given to these plants during late years, since a special society has been formed to further extend their dominion, enhance their beauty, and thereby augment their utility. And well, indeed, do they deserve this attention, for a plant that will flower from September to May is by no means to be despised, and especially when they are of such brilliance, beauty, and (ofttimes) fragrance.

It is often assumed that there is some deep mystery in successful carnation culture. This is altogether erroneous. By constant attention and due observation, the culture of the carnation becomes quite as easy as the majority of plants. Cuttings of the tree carnations, which include the American varieties, should be taken as early in the year as possible. Choose clean side growths a few inches in length, and insert them singly in two-inch pots. If this cannot conveniently be done, a few round the sides of a three-inch pot will root as quickly, but suffer a check when potted into single pots. The soil for the cuttings may be composed of good yellow loam, leaf-soil, cocoanut-fibre refuse, and coarse sand. All these should be passed through a quarter-inch sieve, the proportion being two parts of loam, two parts of leaf soil, and one each of cocoanut-fibre refuse and sand.

A fairly strong bottom heat is desirable, coupled with the close, moist atmosphere of a propagating frame. After inserting the cuttings, water them well, and leave them to drain. This being done, plunge them pot deep in cocoanut-fibre refuse, which is for such a purpose the best plunging material we have. Cover the frame with sheets of glass, which should be removed and wiped three times a day, or turned as many times. In a fortnight or three weeks' time rooting may be expected to have taken place, and some of those showing greater promise may be carefully turned out. In the case of those dibbled singly into small pots, as soon as a rootlet is visible, the young plant may be removed from the case and put into a similar one situated on the staging of the house, but void of direct bottom heat. Wait until the roots of those inserted round the side of a pot are nearly an inch long before removal. After a few days' stay in this cool frame the young plants may safely be set on the open staging, and sprayed with clear soft water twice a day. Some varieties take a considerable time to root, but much depends on the vigour of the cutting, the uniformity of the heat, and the humidity of the atmosphere.

When the small pots are nicely filled with roots the first shift may be contemplated. This will be into a three-inch pot. Let both pots and crocks be quite clean. The following compost will be found suitable: good yellow loam four parts, sifted leaf-soil two parts, brickdust one part, coarse sand one part, some charcoal and the merest dusting of artificial manure. Turn it well over four to six times. To be in an ideal condition it should, when squeezed in the hand, be just sufficiently moist to hang together.

If the desire is to give carnations special treatment soil should be bought specially for them. This may be procured from many parts, but chiefly from Surrey. Almost any nurseryman will supply it. It may be dear at first cost, but it renders the culture of these beautiful plants less precarious. Leaf-soil made solely from oak leaves would improve the compost.

Careful watering and frequent overhead syringings will now form the chief item of culture. The temperature now needed will be of an intermediate character—about 55 degrees, which after a few weeks may be lowered to 50 degrees. In due course the soil will have become permeated with roots and a further shift will be contemplated. This will be into six-inch pots, unless the flowering size is to be eight inches, in which case the shift should now be into five-inch pots. At this potting the soil should be somewhat stronger. Good yellow loam should again form the base, six parts being used to three parts of leaf-soil, two parts mushroom manure, one part of mortar rubble, brick-dust and sand in equal proportions, and a sprinkling each of crushed oyster shell, bone meal, and charcoal, with one three-inch potful of artificial manure to every two bushels of soil. When thoroughly blended this should form an ideal compost.

At this stage the plants may be transferred to a cold frame and be carefully ventilated for some time. The syringing should still be carried on in fine weather, and the plants carefully watered. As the summer approaches, the ventilation may be increased, and eventually the plants may be stood on a moist bed of ashes or gravel outside, shelter from heavy rains being provided by a light frame-work for supporting lights or tarpaulin. This covering should only be put on as necessity arises.

Stakes about three feet long may be inserted, and the shoots duly tied to them. One central stake should be sufficient if the growths are attended to in good time.

With the increase of fine weather the syringe should be kept at full work. To add further to the moisture let the surrounding ground be well sprinkled morning and afternoon. Liquid manure water also will be needed, and should be given for two consecutive days. Then allow three days to elapse and feed for two days with soot water, followed by three more days of clear water. In this way every plant will receive a share of the stimulant, which would not be the case if the feeding were done only on alternate days. A fortnightly top-dressing with some good carnation manure will also produce beneficial results if only about a teaspoonful be given at a time.

About the beginning of September the plants should be housed in a temperature hovering about 50 degrees by night. Syringing will now be abandoned and careful watch will be needed for earwigs, which eat the blooms and bring about their speedy decay. No hard and fast rule can be laid down for stopping tree carnations because the varieties differ greatly, but it is usually a safe plan to top them when approaching six inches in height and again towards June. After the middle of June no further stopping should be done.

Excellent varieties are Enchantress, and its rose-pink form, Mrs. Lawson, Mrs. H. Burnett, White Perfection, Crusader, Winsor, Octoroon, Britannia, Alice Roosevelt, President, Lord C. Beresford, Mikado, Robert Craig, Miranda, Prosperity, Aristocrat, and Marmion.

William F. Rowles.

Bury St. Edmunds.

ATTRACTIVE SHRUBS WITH COLOURED STEMS.

During the winter months we can fully appreciate anything that adds an air of brightness to the garden, a period when the prevailing hue is somewhat sombre. At other periods of the year, when showy flowers and foliage attract in every nook and corner, many things are apt to be overlooked, but in winter anything that adds a touch of colour seldom fails to attract attention. At this season those trees and shrubs which possess bright-coloured bark are specially noticeable, and a note should be made of the most suitable subjects for future planting.

Shrubs with brightly-coloured stems are very effective planted in groups, with a groundwork of some spring-flowering plant such as winter aconite, snowdrop, chionodoxa, or scilla. All these things are very appropriate for carpeting, as the leaves die early, and have disappeared before the shrubs are in leaf. Associated with water, the bright-coloured stems of willow or cornus are peculiarly attractive, the colour on bright days being reflected in the water. As groups in shrubberies they serve to add a note of brightness and warmth, whilst the same may be said of them when used for specimen beds. The majority are free growing, and the colour is usually best when growth is young and vigorous; in fact, it pays to cut some shrubs down to the ground each year to obtain good, free-grown shoots. The colours most noticeable amongst shrubs are red, brown, yellow, and white.

The willows and dogwoods produce the brightest reds. Of the former the red-barked variety of Salix alba vitellina, and a form of S. purpurea, are the best. They should be planted near water, and be cut hard back annually, about the middle of March. Amongst the dogwoods Cornus alba and its varieties, and C. stolonifera are conspicuous. In the case of the former the best to plant are C. alba sibirica variegata and Spathi, as the former has silver variegated leaves and the latter foliage with golden variegation, which makes them beautiful alike in summer when in leaf, and in winter when bare. Other red-barked shrubs are Rubus cratægifolius, Rosa alpina, and Berberis virescens.

Browns are conspicuous in the genus Philadelphus, the dwarf P. Lemoinei being very rich in colour. All are, however, bright. The spiræas are rich in browns, as also are the neillias, stephanandras, Berberis vulgaris, Ribes sanguineum, Rubus spectabilis, Forsythia suspensa, and the various sorts of corylus.

Salix alba vitellina is the best yellow, the bark being richly coloured; a yellow-barked form of S. babylonica also exists, whilst various other willows have bark of a yellowish hue. Amongst cornuses there is a variety of C. stolonifera, called flaviramea, whose chief peculiarity lies in its golden branches.

Amongst white-coloured stems various species of rubus are very conspicuous. By far the most ornamental is R. biflorus. This is strong growing, attaining a height of eight or nine feet. The bark is quite white, and it has been given the name of White-Washed Bramble. The most satisfactory results are obtained by planting it in rich soil, and removing the old growths each year as soon as young ones are a foot or so high. Other brambles with whitish stems are R. lasiostylus, R. neglectus, and R. leucodermis. Bright greens also may be included amongst ornamental stemmed shrubs. The brooms are the most important plants, but Leycesteria formosa, cut down annually, forms strong shoots of a bright green hue.

Some trees are, of course, conspicuous, the birches being the most ornamental. The common Silver Birch, Betula alba, forms a striking object amongst other trees, whilst several other species are attractive.

W. D.

GOOSEBERRIES.

Of all our hardy small fruits none is so useful as the gooseberry, for from early in the season until the leaves are falling in the autumn fruit from these is procurable either in a green state or ripe. When we have a mild spring fruit of some of the earliest kinds is ready for use by the middle of May, and from then onward to October it may be had in good condition. The varieties are too numerous to enumerate. Some nurserymen catalogue as many as one hundred and fifty, but there is a great sameness in many of them, so that the number might be considerably cut down to advantage. No private place requires so many. If a selection of a few of the best of each colour were made, the rest could be dispensed with, taking care to have some both early and late of each.

Gooseberries are grown very well in some districts, every care being taken with them, so that very fine fruit is produced. Especially is this so where amateurs take up their cultivation, as they spare neither trouble nor expense to bring the fruit to the highest state of perfection. When visiting some of their shows the size of the fruit has astonished one, also the colour and quality. It has been no easy task to select the best with three or four dozen dishes, all of the finest quality. It is not, however, as an exhibition fruit that I wish to draw the attention of your readers to the gooseberry, for though some employers take a great interest in their gardens, and find a pleasure in allowing their gardeners to exhibit, there are others who do not care for them to do so, simply keeping their gardens for their own use. As the majority of places are conducted on these lines, it should be the gardener's aim to grow everything to the best of his ability. In the gooseberry we have not only something to supply the kitchen at a time of the year when there is a great scarcity of fresh fruits, but for two or three months some of the varieties provide excellent fruit for the dessert. The green fruit may be bottled, and so preserved for use during winter, as if fresh gathered when ripe it can be made into jam, or otherwise preserved. This being the case, an ample supply should be grown in all gardens where there is likely to be a demand for such fruits.

It is, however, the cultivation, and not the preservation of the fruit that gardeners have to study. Though gooseberries have been grown in our gardens from a very early date, there has been many improved varieties introduced of late years, so that at the present time we have varieties of most excellent flavour when well grown and fully ripe. In order to prolong the season of usefulness those intended to carry fruit till late in the season should be planted against the north side of a wall, and if these are trained in the cordon fashion a greater variety can be grown. The shoots should be taken up diagonally, that the fruit, when ripe, may hang clear of the wood, and may the more readily dry after a shower.

Gooseberries, as everyone knows, are readily propagated by cuttings, so that there is no difficulty in keeping up a supply of young trees of the desired kinds, and when they are required for planting against walls they can be trained for that purpose when young, and so taken up to fill a vacant space should a tree die. As the finest fruit is produced from young trees a good supply of these should always be in reserve, that a piece may be planted each year so as to maintain a good supply of the finest quality. Gooseberries do well as espaliers; the wires should be about six inches apart, and

BEST PLANTS FOR GREENHOUSE.—Nearly 300 pages are devoted to the description, propagation, and culture of the best flowers and plants for the greenhouse in The Amateur's Greenhouse, by T. W. Sanders, price 5s. net, or by post 5s. 6d., from W. H. and L. Collingridge, 148, Aldersgate Street, London.

shoots trained horizontally that the fruit may hang clear. The trees can easily be covered with netting to preserve the fruit from the birds, which, in some places, are far too numerous. When grown in this manner the fruit is much finer than that from old bushes, as ample light and air is admitted. There being but little foliage to shade the fruit a better flavour is obtained, and with more liberal treatment it attains a much larger size.

If exhibition specimens are required all the smaller fruits may be removed early in the season; these will be useful for cooking, so that no waste need be made. Gooseberries, though suitable to any soil, will give far finer results if liberally treated, and very fine fruit indeed may be produced by removing the young shoots, that is, shortening them in the same way as is the case with pears, etc., on walls; and when grown specially for dessert, this plan should be adopted, as the fruits attain a larger size, and, being more exposed to the light, are better flavoured. This is particularly so with those that are required to hang until late in the season. H. C. Prinsep.

Buxted Park Gardens.

CYPRIPEDIUM ANTINOUS.

To the making of new cypripediums there seems to be no end. The merest tyro in orchid culture nowadays raises seedling cypripediums, and, unless the results are absolutely bad, he exhibits the seedlings under various names. All this proves the usefulness and popularity of cypripediums, and also speaks well for their easy culture. But all too often these seedlings are neither really distinct nor any advance upon those already well known, consequently the new name goes to extend the already bulky list, and helps to create confusion. It is another case of believing one's geese to be swans. One thing necessary seems to be the early compilation of lists of too-much-alike varieties. There is, however, always room for a really first class plant, especially in the fast-extending group of winter-flowering cypripediums. One excellent addition is C. Antinous, herewith figured, recently shown by Mr. H. G. Alexander, orchid grower to Lieut.-Colonel G. L. Holford, Westonbirt, Gloucester. This secured a First Class Certificate from the Orchid Committee of the Royal Horticultural Society on December 22 last.

The parents of C. Antinous are Cypripedium J. Howe (or Howes), and C. Actæus. The first-named is itself the result of crossing C. Sallieri with C. villosum aureum, and C. Sallieri is derived from C. insigne and C. villosum. On the other hand, C. Actæus was raised by crossing C. insigne Sanderæ with C. Leeanum superbum, and the latter again was the result of crossing C. insigne Maulei with C. Spicerianum. Here is the parentage set out:

		Sallieri	insigne
		×	×
Antinous	J.Howe	villosum aureum	villosum
	×		
	Actæus	insigne Sanderæ	
		×	insigne Maulei
		Leeanum superbum	×
			Spicerianum

The dorsal sepal of C. Antinous is white, with a green base, and purple spots over the lower half. Both lip and petals are bright greenish yellow, and the whole flower is very attractive and bold.

C.

Everyone interested in a garden should obtain a copy of the Alphabet of Gardening, by T. W. Sanders. Thoroughly practical information is given as [illegible] seed sowing, planting, potting, budding, grafting, forcing, hybridising, etc., with explanatory diagrams. Price 1s. 6d. net, by post 1s. 9d.; cloth, 2s., by post 2s. 3d., from W. H. & L. Collingridge, 148 and 149, Aldersgate Street,

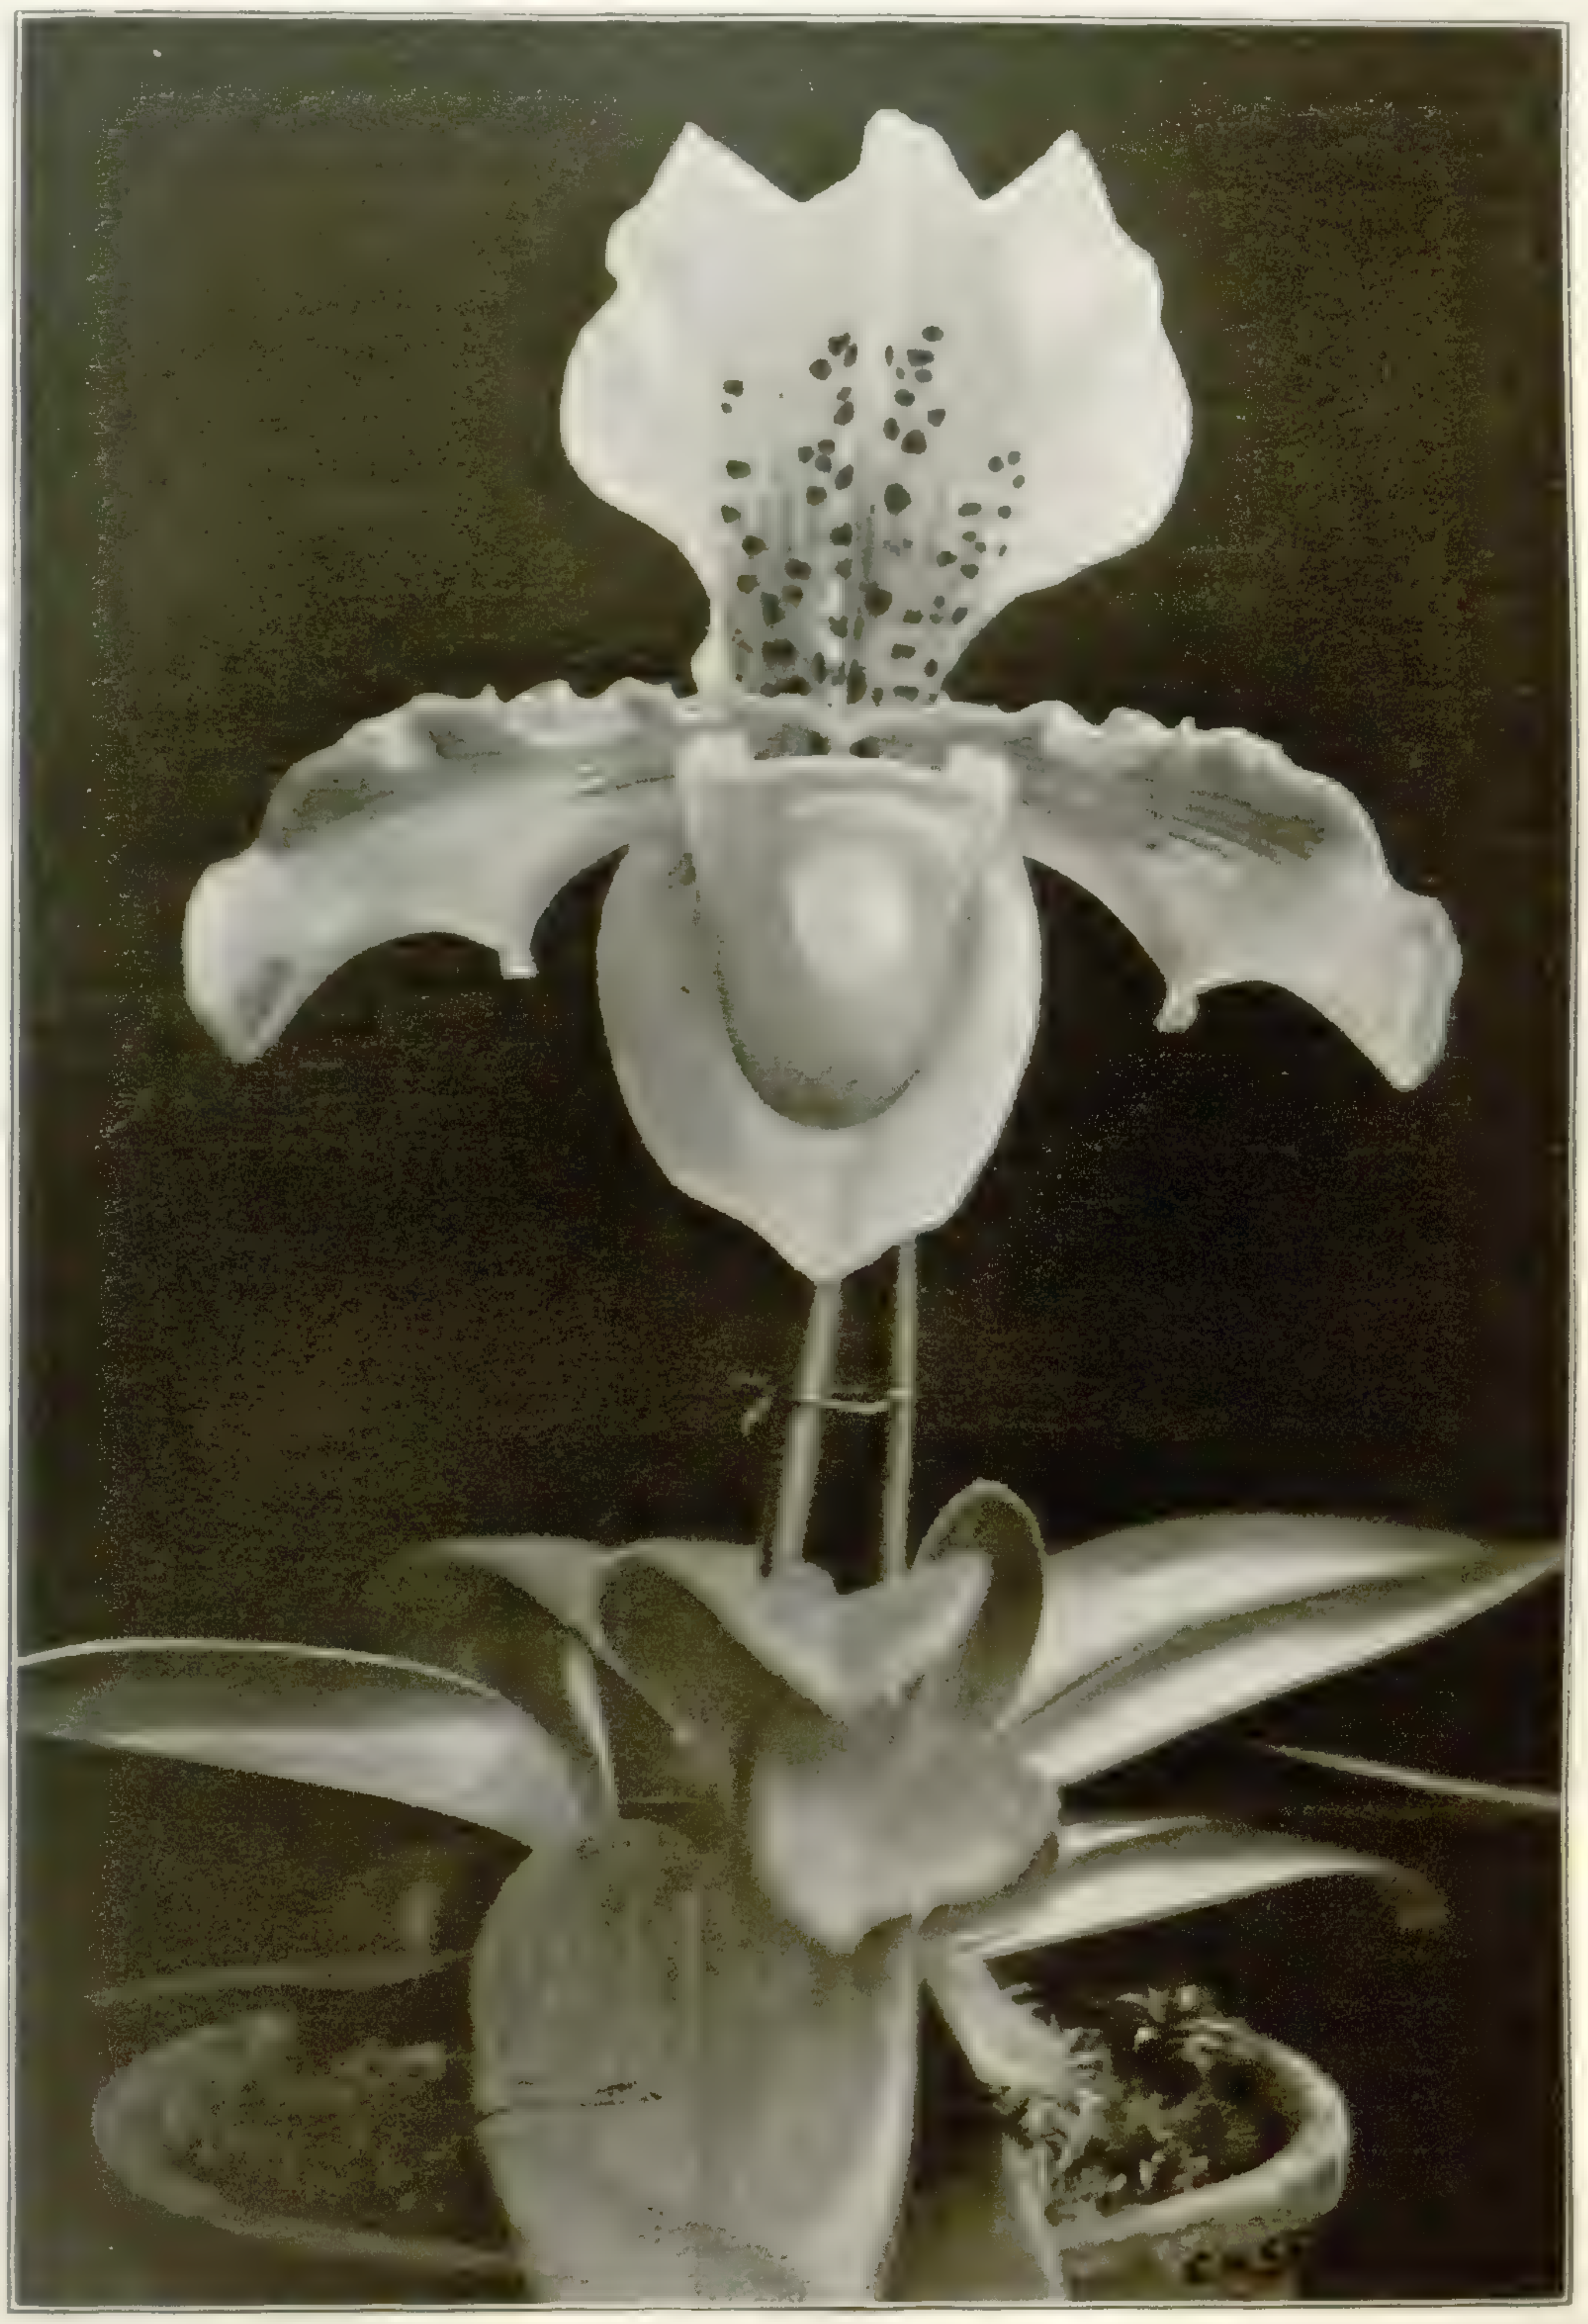
WORK FOR THE WEEK.

◆

THE ORCHID HOUSES.

GENERAL REMARKS.—The exceedingly changeable weather during the past three or four weeks has, more or less, limited the general work in the orchid houses. Opportunity should now be taken to attend to any cleaning that may be necessary. With the strong gales that have been accompanying the cold weather in the North, a more than ordinary amount of artificial heat has been required, even to maintain the minimum temperature in each division, and this, with the drier atmosphere created, has a tendency to promote red spider. Close observation is therefore necessary, and when the pest is found steps must at once be taken to check it. There is no better method of preventing the spread of red spider than carefully spraying the leaves. Small yellow thrips are perhaps the worst pests the orchid-grower has to contend with, especially those which attack cypripediums. I never hesitate to dip the plants at any season of the year when thrips have been observed. Where plants have to be dealt with that have become so infested that the foliage is disfigured, the best method is to dip at intervals of a week for about a month, and then fortnightly until one is satisfied the plants are free from the pests. Prevention is better than cure, and we find it advisable to spray the plants once or twice a month in all the warm divisions, choosing a day when the outside conditions are favourable for the purpose.

PREPARATORY WORK. — During the delay caused by the unfavourable outside conditions, preparations should be made to facilitate the various operations that will soon have to be performed. A supply of sphagnum moss should be secured, carefully picked, washed, and put ready for use. If stored in a cool, damp place and turned over once or twice a week, it keeps in good condition for a long time. Peat should also be pulled to pieces. We usually have sufficient pulled now to last through the potting season. The bracken roots taken from the peat should be preserved, for there is nothing more serviceable for drainage purposes for practically all kinds of orchids. Care must be taken to have these roots properly dried. If there is the least trace of green, woody, or sappy substance remaining in them when used for drainage, fungoid growth appears, which quickly spreads to the potting compost and produces undesirable conditions. Loam, which is desirable for many of the terrestrial species of orchids, should also be selected and made ready; good fibrous turfy loam, with the fine soil removed, is the best for the purpose, and this should be stored in a place where it may become warmed and ready for use. Care must be observed to see that the loam, after being picked, does not become too dry.—H. J. Chapman, Oakwood Gardens.



CYPRIPEDIUM ANTINOUS.
Flowers white and purple and greenish yellow.

CONSERVATORY AND GREENHOUSE.

CONSERVATORY.—Continue to keep the conservatory bright by bringing in the forced plants as they come into bloom, and even if it is not necessary each week to turn everything out and put fresh plants in, it must be borne in mind that a good picking over does a deal of good, and if at the same time the plants are given a turn round it will tend to keep them in good shape, and where the glass is only on one side this turning operation will bring the best side of the plant forward.

MALMAISON CARNATIONS. — Where these have not been shifted into their flowering pots the work should be done at once, though preferably they ought to be potted before Christmas, but it not delayed later than the first or second week in February they will still have time to make good roots before commencing to grow freely. They should be potted in an open compost of loam, leaf-soil, and sand, with a good quality of lime rubble added, and a little bonemeal will be beneficial. Where the soil is very heavy, or is likely to contain many wireworms or other injurious insects, it is as well to sterilise it some time before use. If the plants are attacked by rust they ought to be well picked over, removing all badly infested parts and burning them, then dipping the plants in a solution of sulphide of potassium or some other approved fungicide. The potting should be done firmly, keeping the collar of the plant fairly well out of the soil, because in some localities Malmaisons are troubled with stem rot. They should then be placed in a house where they can have all the light and air possible, and be watered with the greatest care.

WINTER-BLOOMING CARNATIONS will now be growing somewhat freely, and if good flowers are wanted right through the spring a general overhauling will be advisable, cutting back all flower stems to where a growth is pushing forward, and at the same time tying in all young shoots, afterwards giving all the plants a slight top-dressing of soil with a little approved carnation manure added.

BEGONIAS AND GLOXINIAS.—Where an early batch of these is required they should be started at once. All old soil should be shaken from the tubers. I prefer to place them in boxes, an inch or two apart, with barely sufficient leaf-soil or some other light compost to cover them, placing the boxes in a warm house until growth commences. As soon as root action is fairly free they should be lifted from the boxes with as much of the soil adhering to them as possible, and be potted at once into their flowering pots, using a compost somewhat lighter than would be used for later batches. Where greenhouse room is somewhat limited I have found a shelf in a warm vinery a very good place for forwarding them, but they should not stop there too long, as a somewhat drier atmosphere is necessary, particularly in the case of the begonias.

AMARYLLIS.—Batches of these showy and easily-grown bulbous plants may now be introduced into heat as required, and where possible they should be plunged to the rim in a mild hotbed of leaves, after they have been top-dressed with loam, sand, and bonemeal. They will require a thorough soaking of water either just before or just after plunging, and then very little will be needed for some time, a morning and afternoon syringing providing the necessary moisture.—THOMAS STEVENSON, Woburn Place Gardens.

THE FLOWER GARDEN.

HERBACEOUS BORDERS. — No garden of any importance is considered to be complete in these days unless it devotes some considerable space to the cultivation of herbaceous plants, and unquestionably when these are effectively planted they are not only extremely beautiful through the spring, summer, autumn, and a good part of the winter, but they also supply a wealth of material that is far better for cutting than that of many of the more tender plants. The mistake very many people make, and especially where room is of little consideration, is that they do not allow sufficient space when setting out the permanent borders, the result being a crowded and entangled mass, without any pleasing effect. In arranging for new borders one should take fully into consideration the height and sizes of the various subjects which one intends to employ, and the larger the masses or groups within reason of each kind or variety the better. Every care should be taken to arrange the colours of the various subjects so that they harmonise, and at the same time endeavour to spread over the borders as far as possible plants that will flower at various seasons of the year. As many of the stronger-growing plants are very deep-rooting, the ground should be thoroughly trenched and manured as the work proceeds.

RENOVATING BORDERS.—To keep old borders in good order they must be given attention annually at this season of the year, and frequently extreme measures have to be taken, by dividing and checking the growth of many of the more robust kinds, or the result would be that many of the more choice and delicate subjects would soon become overgrown and crowded out. Fork over the border with a small fork, and give a good top-dressing of well-decayed old hot-bed material. It is most important that the plants be kept correctly labelled, no small trouble where large collections are grown, but it is almost impossible, however well versed one may be in this large and rapidly-increasing department, to be able to ensure their correct nomenclature without labels. There are very many kinds of labels now in use, and, though in my opinion there is plenty of room for improvement, I have found none more effective and cheap than those made of zinc. The chief difficulty is that the writing only remains legible for twelve months. I have been trying, with a certain amount of success, white paint on these, and then applying a coat of varnish, which so far seems to answer well.

ROCK PLANTS.—These should be carefully looked over, and the same thing applies here as to herbaceous plants in relation to keeping within bounds the stronger-growing kind, while every encouragement should be given to those of weaker constitution by affording them the best possible sites and a good top-dressing. — E. BECKETT, Aldenham House Gardens.

FRUITS UNDER GLASS.

EARLY VINES.—Where these are breaking, and are seen to be breaking regularly, they should be at once tied up into position. The temperature may be raised to 60 degrees at this stage, allowing it to run up to 70 degrees by sunheat. See that the border does not lack water, and have it syringed twice daily. All vines at rest should be kept absolutely cool, and heat should not be turned on during house washing, as a day or two of heat may cause the sap to rise and so start bleeding. All houses should be thoroughly cleaned, as previously advised.

FRUIT TREES IN POTS.—These should be kept outside until wanted for forcing, but in the case of plums a sharp look-out for birds will be necessary, unless there is wire protection. When the trees are required they should be thoroughly cleansed, have the pots washed, labels rewritten, the surface soil removed to the roots, and given a good top-dressing of rich maiden loam which has been stacked a year; this, mixed with some bonemeal, will satisfy the trees for the time being. If any tree is thought to be very dry it should be placed in a tub of water. Pot trees require great care in watering, especially in the early stages of growth; therefore, perfect drainage is absolutely necessary. Pot trees have been in great demand during recent years, as they can be grown in a house or houses for a few months, and be then turned outside to finish their crop, and the house devoted to other purposes

FIGS IN POTS AND PERMANENT BORDERS should now receive the pruning necessary, which means cutting out all gross or unripened or unfruitful wood. If the border is too rich this will cause unfruitful growth, and this can only be remedied by curtailing the food supply. Clean the house and trees, and have the ventilating gear and valves oiled and cleaned. Proceed then and tie in the growths with small string, keeping them straight, quite six inches apart. When the trees are finished give the floors a final clean, and you have the house ready for starting.

STRAWBERRIES.—Keep the fruiting plants near the glass, especially those showing the flower stems, and do not force overmuch; a temperature of 55 degrees will be quite high enough to bring them along with success. Another batch may now be put under cover. Remove away all loose soil and decayed leaves, and give a top-dressing if necessary. Only bring in as many as can be readily dealt with. Royal Sovereign and Laxton's Noble are two good varieties for early use. A temperature of 45 to 50 degrees will be enough for the first fortnight. Stored plants should have the lights removed on all mild days, where these have been the means of protection.

PEACH HOUSES.—In the early house proceed carefully with artificial heat at this stage, keeping the temperature as near 50 degrees as possible. The trees will perhaps be longer in flower, but they gather strength thus, which means a good set, and they can be forced harder after this stage. Admit a little air to the house on all fine days, and close with a general spraying down of the floors, etc. The late houses must be cleansed and the trees pruned and dealt with as already recommended for the early house. Retain as much small fruiting wood as possible, and cut out the old and useless. do not tie the branches closely together, but allow for proper development of the foliage. —W. A. COOK, Leonardslee Gardens.

URCEOLINA PENDULA.

This is called the Urn Flower, because of the shape of the blooms, that are of a bright yellow colour, and hang around the top of the flower stems like the lustre ornaments which used to be considered indispensable in many households. Urceolina pendula is a bulbous stove plant, and deciduous when at rest. With good treatment it is strong growing, and makes very large bulbs, and the great art in making the plant attractive is to cultivate as many bulbs as possible in one pot.

Sometimes the urceolina is spoken of disparagingly because, we will say, there is only one spike of flower in a six or seven-inch pot; but to see this subject in all its glory it must be cultivated in large pots, twelve or fourteen inches, with as many bulbs in as possible. The result is twelve or eighteen spikes of flowers, which cheer us in October, November, or December.

The bulbs should be separated in March or April, the compost suiting them being a rich mixture of good yellow loam, leaf-mould, and very rotten stable manure, with plenty of silver sand. After flowering, the pots should be turned on their side on a shelf in a warm position in the stove or similar place, and the soil be kept quite dry until the bulbs show sign of growth from the apex. When growth is half an inch long the plants should be dealt with according to requirements, either separated or left for another season in the same pot.

They are soon in active growth, and require a good light position, with plenty of warmth and moisture, until, towards autumn, the foliage shows signs of dying down, when a very small quantity of water will suffice. A few weeks after the foliage has died away the flower spikes begin to appear, and then a very careful watch must be kept for snails, as these marauders will level the spikes as fast as they appear from the bulbs if allowed a free run.

Cheshire. W. M

RED OR GRIZZLY GRAPES.

To my astonishment, Mr. Editor, no one, thus far, has had the temerity to dispute the autocratic reply from Mr. Molyneux to Mr. C. H. Curtis's well-timed and practical article under this heading (see "G. M.," October 24, 1908, p. 796). Worth growing? Of course they are, and well worthy of it too, is the answer of one who has had practical proof of their value. Mr. Curtis was quite right, Mr. Molyneux, when he penned his article on "Red or Grizzly Grapes." Why, in the name of common sense, is it so imperative that grapes should be either black or white? There are no black or white grapes that can surpass, and very few to equal, the Grizzly Frontignan, the Duchess of Buccleuch, or the Muscat Champion for rich, piquant flavour. True, they may not be what are termed "exhibition" grapes, neither do they appeal to the public who are not conversant with actual quality, as against size and appearance. With the rage for the big chrysanthemum, the big onion, the big pear, and the big apple has come the rage for big grapes, as represented by big and sometimes unwieldy bunches, and by big berries too.

Is Mr. Molyneux aware of the fact that big bunches are wasteful from the point of utility? Or, again, of the fact that many connoisseurs of fruits, grapes, of course, included, do not care for big examples of any kind? Or that big-berried grapes, such as Gros Colmar and Gros Maroc, are passed by for the smaller and more luscious grapes, such as Grizzly Frontignan and the others already named? From the point of mere colour alone, where should we be if we relied upon such worthless apples as Worcester Pearmain for the dessert? All it has to recommend it is its colour and its cropping qualities sometimes, hence it is what may be termed a market apple, and a market apple only. This is only quoted to illustrate that appearance and cropping qualities must not be placed before quality for the dessert.

Since I read Mr. Molyneux's reply on this subject, and that, too, given in such an emphatic manner, I have turned up "Thompson's Book on the Vine" (the author wrote from the gardener's standpoint, and placed quality in the front rank, knowing from practical experience, covering many years, that it was the correct thing to do), than which there is not a more practical or condensed work extant. In it the author, in giving selections of twelve varieties for forcing purposes, includes two of Duchess of Buccleuch and one Grizzly Frontignan (both of these coming under the severe condemnation of Mr. Molyneux). Three out of twelve is not a bad percentage (25 per cent.), is it, Mr. Editor?

As regards flavour, I remember some years ago that the Duchess of Buccleuch won the first prize at the Royal Caledonian Fruit Show. If I were going to compete again, and flavour was imperative, I should show the Duchess or the Grizzly Frontignan, and have no fear of the result against such varieties as Mr. Molyneux would have us grow. Small-berried grapes are, as a rule, better from the point of flavour than the large-berried ones. As an instance, we know which berries to select for flavour in a bunch of Muscats where there are some of the small high-coloured berries present. I recently had a note from a well-known nurseryman, who remarked that "the present rage for big grapes was one of the most foolish which has ever existed; it arises from the fact that half the British public has little or no palate, and one fruit is about as good as another to it."

The late Mr. A. Barron, who also wrote, and with authority too, upon the vine, demonstrated in the trials at Chiswick that the red and grizzly grapes came out well up in the list, if not at the actual top. In conclusion, let me add that for home use neither large bunches nor large berries count with the connoisseur. Growing for exhibition or for market mere size and appearance tell, as we know.

GRIZZLY FRONTIGNAN.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

Royal Horticultural Society.

The exhibition held on January 26 was not a large one, but it was interesting and well attended.

FLORAL COMMITTEE.

Messrs. Sutton and Sons, Reading, submitted a large group of cyclamen, than which there are few more useful flowers at this season of the year. The Reading firm has worked long and successfully in the improvement of habit, form, and colour of these plants, and on this occasion they set up batches of such excellent varieties as Salmon Pink, Giant White, Giant Crimson, Giant Mixed, Vulcan, and the interesting White Butterfly. The plants were finely grown and splendidly flowered, and the bold masses of large, superbly-formed flowers, produced a rich display of colour. Messrs. H. B. May and Sons, Edmonton, contributed a large group of davallias, and these, showing a wonderful diversity of character, were greatly admired. Some of the specimens of D. dissecta elegans, D. polyantha, D. Mooreana, D. fijiensis were of considerable size, and were especially attractive.

A beautiful exhibit and a large one was admirably set up by Mr. W. H. Page, Tangley Nursery, Hampton. It consisted of big sheaves of fine flowers of Lilium longiflorum, L. speciosum rubrum, L. s. album, a splendid lot of vases of popular perpetual carnations, and a beautiful lot of flowers of the golden daffodil Golden Spur, in fine condition. Altogether a delightful exhibit. A brilliant display of carnations was made by Messrs. W. Cutbush and Son, Highgate, and particularly fine were the large vases of Mrs. Burnett, Mrs. T. W. Lawson, White Perfection, Victory, Enchantress, Jessica, and Robert Craig. The same firm showed a group of forced magnolias, Prunus triloba, etc., and some charming early irises.

Mr. H. Burnett, Guernsey, exhibited beautiful carnations, notably Marmion, Mrs. H. Burnett, the yellow Fortuna, Mikado, Aurora, Britannia, and Robert Craig. Mr. H. Chapman, Guldeford Lodge, showed a charming lot of freesia flowers, including F. Chapmani, F. Chapmani Improved, the Rajioneri hybrids, and several very interesting seedlings of his own raising, all delightfully fragrant.

Messrs. Barr and Sons, Covent Garden, showed a number of interesting early flowers, such as snowdrops, crocuses, iris, narcissi, and freesias. Mr. Bain, gardener to Sir Trevor Lawrence, Bart., Dorking, staged two vases of wonderfully bold and beautiful anthuriums of the Andreanum type, the colours being scarlet, crimson, pink, and white.

Carnations in great variety were exhibited by Messrs. Hugh Low and Co., Bush Hill Park, Enfield, and they showed Rose Pink Enchantress, Aristocrat, and the more popular varieties. Mr. G. Reuthe, Keston, submitted some very pretty crocuses, hellebores, saxifrages, etc. Winter-flowering plants were well shown by Messrs. James Veitch and Sons, Chelsea, these including batches of the blue Coleus thyrsoideus, begonias, camellias, Primula Kewensis, and Aphelandra aurantiaca Roezli. Alpine flowers and shrubs were displayed by Messrs. J. Cheal and Sons, Crawley.

A group of splendidly grown and beautifully flowered plants of the graceful and brilliant Euphorbia jacquiniæflora was arranged by Mr. Prime, gardener to the Marquis of Salisbury, Hatfield House, Hatfield, and the same exhibitor set up a group of finely-grown specimens of the beautiful Begonia Gloire de Sceaux. Mr. Russell, Richmond, sent Jasminum primulinum.

BATH'S
GOLD MEDAL
SWEET PEAS.

We grow many acres of Sweet Peas and supply seed to all the large wholesale houses.

The following list contains the best Novelties in Cultivation.

The number of seeds and price per packet are indicated after each variety.

American Novelties for 1909.

Apple Blossom Spencer, deep rosy pink, a distinct variety (20), 6d.
Asta Ohn, lavender tinted mauve, beautifully waved (10), 6d.
Dainty Spencer, pale primrose, changing to white, with pink edge, very large flowers (20), 6d.
King Edward Spencer, bright crimson, enormous flower, beautifully waved (10), 6d.
Mrs. Chamberlain Spencer, white, marked bright rose (20), 6d.
Mrs. Routzahn, deep cream ground, with decided rose edge, large flower of perfect form (10), 6d.
Princess Alice Spencer, a lovely shade of lavender, beautifully waved (20), 6d.
Princess Katherine Spencer, pure white, beautifully waved (20), 6d.
Queen Victoria Spencer, deep primrose, flushed rose, extremely large (10), 6d.
Ramona Spencer, clear white, delicately lined blush pink (10), 6d.
Tennant Spencer, purplish mauve, much larger and finer than Marquis (10), 6d.

English Novelties.

CHIEFLY HOME-GROWN SEED.

Audrey Crier, pale salmon pink, beautifully waved (10), 1s.
Beauty, light blush pink, an extremely fine Spencer (20), 6d.
Bobby K, delicate blush, large waved flower (20), 6d.
Chrissie Unwin, light scarlet, a very large flower (12), 6d.
Clara Curtis, creamy yellow, beautifully waved (12), 6d.
Dudley Lees, rich dark maroon, fine large flower (25), 6d.
Elsie Herbert, blush white, with deeper edge (10), 6d.
Etta Dyke, the largest waved pure white (12), 6d.
Evelyn Hemus, creamy yellow, edged pink (10), 6d.
Florence Morse Spencer, pale rosy pink, a grand flower (50), 6d.
H. J. R. Digges, deep claret, a very large flower (12), 6d.
Hannah Dale, deep rich maroon, very large flower (12), 6d.
Horace Skipper, deep rosy pink, large flower, beautifully waved (12), 6d.
James Grieve, sulphur yellow self, extra fine (20), 6d.
Lady Althorp, white edged pale fawn, fading to pure white, waved (20), 6d.
Maggie Stark, brilliant cerise and madder lake (12), 1s.
Marjorie Willis, deep rose, waved (12), 6d.
May Perrett, clear flesh, tinted buff, a lovely shade (12), 6d.
Menie Christie, purplish carmine, waved (12), 6d.
Mima Johnston, bright rosy carmine, slightly shaded salmon (12), 6d.
Miss E. F. Drayson, rich scarlet, large waved flower (12), 6d.
Nell Gwynne, deep cream, suffused bright pink, a lovely variety (10), 6d.
Olive Ruffell, deep cream ground, heavily suffused bright red, a lovely variety (10), 6d.
Paradise Red Flake, white, marked bright red (20), 6d.
Prince Olaf, white, marked bright blue, very distinct (20), 6d.
Prince of Asturias, deep chocolate, beautifully waved (12), 6d.
Purity, extra large pure white, waved, a flower of great refinement (20), 6d.
Regina, deep maroon, almost black (25), 6d.
Rosie Adams, rosy mauve, large flower, beautifully waved (10), 6d.
Sutton's Queen, primrose, edged pink, very beautiful flower (12), 6d.
St. George, brilliant cherry red, a fine waved flower (15), 1s.
The Marquis, deep mauve, beautifully waved (12), 6d.
Zero, a fine waved white, very pure, blooms a fortnight before other varieties (50), 6d.

Any ten 6d. packets for 4s., post paid.

One packet of each of the above 44 varieties for 16s. 6d. post paid.

R. H. BATH, Ltd. (Dept. H),
The Floral Farms, **WISBECH.**

A useful late-flowering chrysanthemum of medium size, reflexed Japanese, substantial and of rich golden colour, was shown by Messrs. Robinson and Headey, Dunstable; it is named Golden Sunset (A.M.)

ORCHID COMMITTEE.

Mr. Alexander, orchid grower to Lieut.-Colonel Holford, Westonbirt, Tetbury, Gloucester, showed the pretty Sophro-lælio-cattleya Danæ Holfordiana, Cypripedium Earl of Tankerville (A.M.), C. Alabaster, and the beautiful Golden Lælio-cattleya Golden Oriole var., with large bright yellow flowers. Mr. A. W. Jensen, Lindfield, Haywards Heath, set up a charming group of white and blush forms of Odontoglossum crispum. From Mr. M. W. Thompson, Stone, Staffs, came the handsome Cypripedium Our Queen, a cross between a dark form of C. Leeanum and C. Stevensi (A.M.) A beautiful form of Cattleya Trianæ named The Premier, with lovely broad rosy petals, was shown by Mr. Hopkins, gardener to Francis Wellesley, Esq., Woking.

Messrs. Charlesworth and Co., Haywards Heath, exhibited Sophro-lælio-cattleya Marathon Vesuvius (F.C.C.), a bright flower derived from S. l. Psyche and C. Empress Frederick; Lælio-cattleya Felicia (F.C.C.), a magnificent purple-lipped cross between L.-c. Haroldiana and C. Trianæ; Cymbidium Woodhamsianum, Brasso-cattleya Cliftoni, and the chaste Odontoglossum Armainvillierense album. Mr. J. Collier, gardener to Sir J. Colman, Bart., Gatton Park, Reigate, showed a few interesting botanical orchids, Cœlogyne Colmani, Phaio-calanthe Colmani, and Spathoglottis Colmani. Mr. Forster Alcock, Northchurch, sent Cypripedium Beryl, and C. Hera, Euryades New Hall Hey var. (A.M.), the latter a bright and bold var.

Mr. F. J. McBean, Plumpton, showed a few good cattleyas and odontoglossums. Messrs. Cypher and Son, Cheltenham, contributed a very handsome group of cypripediums and odontoglossums, the former being very fine, and including C. Mrs. W. Mostyn, C. Lathamianum Rex., C. aureum Virginale, C. Master-exul, and the pretty C. Dowlingianum. Messrs. Hugh Low and Co., Bush Hill Park, Enfield, had a small collection of cypripediums associated with Platyclinis glumaceum, Brasso-cattleya Madame Charles Maron, and Cattleya Trianæ.

FRUIT AND VEGETABLE COMMITTEE.

A large collection of well-preserved apples, all plump and bright, was well staged by Messrs. J. Cheal and Sons, Crawley. There were excellent baskets of the new long-keeping Encore, Lane's Prince Albert, Crawley Reinette, Newton Wonder, Lord Derby, Annie Elizabeth, and Bramley's Seedling. Mr. C. Foster, University College Gardens, Reading, showed seakale cuttings ready for planting, and some very fine crowns, one year old, from similar cuttings. He also showed some forced Linnæus rhubarb, and forced chicory with part of root attached.

Mr. Gentle, gardener to Mrs. Dennison, Little Gaddesdon, Berkhamsted, showed some perfect Intermediate and other carrots, Maltese parsnips, and beet, as well as a fine collection of Cocoanut, Record, and Ailsa Craig onions, and some two dozen dishes of very excellent potatoes that included fine specimens of Factor, King Edward VII., Duchess of Cornwall, Satisfaction, etc.

In the competitive classes Mr. H. Juniper, gardener to Mrs. Trotter, Dyrham Park, Barnet, won first prize for both seakale and forced rhubarb. Mr. E. Beckett, gardener to the Hon. Vicary Gibbs, was awarded first prize for four varieties of home-grown salads, showing Batavian endive, Blood Red beet, Christmas Salad chicory, and mustard and cress.

CERTIFICATES AND AWARDS.

First Class Certificate.—To Sophro-cattleya Marathon var. Vesuvius, from Messrs. Charlesworth and Co., Haywards Heath. To Lælio-cattleya Felicia, from Messrs. Charlesworth and Co., Haywards Heath.

Award of Merit. — To Chrysanthemum Golden Sunset, from Messrs. Robinson and Headey, Dunstable. To Cypripedium Our Queen, from Mr. W. Thompson, Walton Grange, Stone, Staffs. To Cypripedium Earl of Tankerville from Lieut.-Colonel G. Holford, Westonbirt, Tetbury, Gloucester (grower, Mr. H. Alexander). To Cypripedium Hera Euryades, New Hall Hey var., from Mr. Forster Alcock, Northchurch.

MEDALS.

Silver-gilt Flora.—Mr. W. H. Page, Hampton, carnations and lilies; Messrs. H. B. May and Son, Edmonton, davallias; Mr. Prime, gardener to the Marquis of Salisbury, Hatfield, begonias and euphorbias.

Silver-gilt Banksian. — Mr. Gentle, gardener to Mrs. Dennison, Little Gaddesdon onions and potatoes.

Silver Flora.—Messrs. W. Cutbush and Son, Highgate, carnations and plants; Mr. H. Burnett, Guernsey, carnations; Messrs. Sutton and Sons, Reading, cyclamens; Messrs. James Veitch and Sons, Chelsea, winter-flowering plants; Messrs. Charlesworth and Co., Haywards Heath, orchids.

Silver Knightian.—Messrs. J. Cheal and Sons, Crawley, apples.

Silver Banksian.—Messrs. Hugh Low and Co., Bush Hill Park, Enfield, one for orchids and one for carnations; Mr. L. R. Russell, Richmond, shrubs; Messrs. J. Peed and Son, Streatham, alpines; Mr. H. Maude, R.H.S. Gardens, Wisley, lantern slides, representing flowers, by colour photography; Messrs. J. Cypher and Sons, Cheltenham, orchids; Mr. Jansen, Lindfield, orchids; Mrs. C. Foster, Horticultural Department, University College, Reading, forced vegetables.

French Horticultural Society of London.

Under the presidency of Sir Albert K. Rollit, the above society held its annual dinner at the Café Royal, Regent Street, on Saturday, January 23. There was a good attendance, and by far the larger number of the persons present were Britishers, representing the seed and nursery trades, public and private gardening, and the horticultural Press.

After an excellent dinner the toasts of "The President of the Republic" and "The King" were duly honoured, and then Sir Albert Rollit proposed "Success to the French Horticultural Society of London." In an excellent and humorous speech he compared the horticulture and the characteristics of France and England, and pointed out that each could learn from the other, and that the present friendliness existing between the two nations was a great factor for the preservation of peace in Europe. The usefulness of the society, and its progress from 12 to 700 members was referred to, and Mr. G. Schneider, the president was complimented upon the success attained. Mr. Schneider responded, and said that M. Phillipe de Vilmorin had consented to hold the office of honorary president.

The only mistake in connection with a very pleasant function was the inordinate length of the programme, many items of which had to be omitted. Mr. Schneider proposed, "English Horticulture," to which Mr. D. Ingamells responded, and then proposed "Past Chairmen," to which Mr. T. Bevan responded. Mr. C. Harman Payne gave "The Officers of the Society," and M. Ripard responded.

During the evening, the members of the society presented Mr. Schneider with a handsome silver rose bowl as a token of their regard.

Wyken Pippin Apple.—The remarks upon this apple, on page 46, prompt me to write that there is an old standard tree growing in these gardens which has cropped heavily for many years. This last season we stored about four bushels of the best fruits, which are keeping well, and average seven and a-half inches in circumference. Contrary to the experience of your correspondent, our fruits are very juicy, and of good flavour, and much appreciated here. In my opinion, this variety is far too good to be discarded. I may add the soil here is a heavy loam, resting on very stiff clay.—J. BOXALL, Russ Hill Gardens, Charlwood.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

HISTORY OF THE SWEET PEA.—E. P. L., Carlisle:—We are glad to learn the Carlisle Society has affiliated with the National Sweet Pea Society. With regard to the history of your favourite flower, you will find the best account yet published in the new and enlarged edition of "Sweet Peas and their Cultivation," a work written by the Hon. Secretary of the N.S.P.S., and one that also contains very practical information relative to the culture of sweet peas, as well as their exhibition, raising new varieties, etc. Cloth-bound the book is 1s. 8d., post free, from Messrs. W. H. and L. Collingridge, 148, 149, Aldersgate Street, E.C.

APPLE BLOSSOM WEEVIL.—F. E. S., Cheltenham.—One very curious thing about the apple blossom weevil is that in the case of adjoining orchards one may be infested and the other free; even in the one orchard a certain area may be infested and the rest free. Other points are that the apple blossom weevil does the most damage when the apple blossoms open slowly, and that the early and the very late flowering apples suffer the least. The weevils winter under fallen leaves, earth clods, bark, etc., and in early spring they come forth and fly to or ascend the trunks of the apple trees. Very soon the females commence to lay their eggs; this is done by boring a hole in the flower bud and pushing through it an egg, right into the centre of the flower. The maggots hatch out in eight or ten days, and feed upon

IF YOUR GARDEN IS PEST-RIDDEN USE "KILOGRUB."

Prompt treatment with "Kilogrub" is the only sure way to free your soil from insect pests.

Two or three ounces of

"KILOGRUB"

to every square yard—well distributed and worked into the soil—is sufficient to destroy all insect pests.

"Kilogrub" gives off chemical fumes which are deadly in effect upon insect life, but are absolutely harmless to plants—it has been thoroughly tested—hundreds of gardeners having tried it with complete success on severely afflicted gardens.

For cash with order we will forward 1 quart of each of the above varieties.

i.e. Five quarts in all for 7/6. Carriage Paid.

ALEX. DICKSON & SONS, Ltd.,
53, ROYAL AVENUE, BELFAST.
66, DAWSON ST., DUBLIN.

the essential organs of the flower, causing so much damage that as soon as the petals open growth ceases, and the flower withers and dies, and, of course, no fruit is formed. Clean cultivation and winter spraying will do much to reduce or prevent infestation, while sharply jarring the trees before the larval and pupal stages are over will rid the trees of the pest. A white cloth must be laid under the tree to catch the weevils and dead blossoms, all of which should be burned at once. It may be necessary to execute this operation a second time, allowing a day or less to elapse before the second attempt.

SOWING SWEET PEAS IN POTS.—J. B., Amersham.—We have pointed out previously that there is a great danger in sowing sweet peas in pots at a too early date. Any time from now until the middle of February the seeds may be sown, but if very mild weather prevails then there is a probability that the early-sown batch will become drawn, and possibly starved also, unless you have ample frame accommodation in addition to the greenhouse, and treat the plants with great care during early April. If very severe weather in April compels one to defer planting, then the trouble arises in the case of the very early-sown plants. We strongly believe in sowing the seeds in pots, in a cool greenhouse, from the 10th to the 15th of February; this is not early enough to cause trouble by semi-starvation, nor is it too late for the production of strong, well-rooted plants by mid-April.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—In our report of the annual meeting of this institution we have not room to give the numbers of votes recorded, but, as we invariably receive requests for full particulars, we give them in this column: Emma J. Whitehurst, 4,746; John E. Anstey, 3,038; Matilda Ings, 2,946; Henry Heims, 2,908; Thomas Jones, 2,903; John Burton, 2,883; Henry Cooper, 2,855; Wm. Gardiner, 2,825; Jane Noble, 2,800; Harriett Helman, 2,681; Wm. Cope, 2,618; Henry Gage, 2,569; Thos. C. Cushion, 2,494; Edward Tibbles, 2,449; George Lawrence, 2,429; Joseph Throp, 2,359; Joseph Talmage, 2,350; Wm. Reynolds, 2,303; Edwin Ratlin, 2,292; Thos. Chapman, 2,222; Henry Sawyer, 2,215; Wm. HELLEBORE WASH.—J. P. P.: Tewkesbury: We very much appreciate your remark that one should look ahead in the matter of preventives and remedies, quite as much as in the matter of ground work and crop rotation: Not seldom we receive a query from someone whose plants are suffering from a bad infestation of some pest, the pest was not noticed, or if noticed was disregarded until the infestation assumed alarming proportions, and then, post haste, a request for information is sent to us, probably imploring us to send per return of post the needful recipe for a mixture that will annihilate the pest. In most cases when the need is as desperate as this the writer forgets to send his address, and the note arrives on a Wednesday evening, too late to be dealt with in the current issue. It is far better to look ahead, and also to seek information that may be of service in the future. It is also advisable to keep reference works on a handy bookshelf: for instance, the "Gardening Year Book" gives descriptions and illustrations of and remedies for a large number of fungoid and insect pests, besides a large amount of other horticultural information. It will be sent, post free, for 1s. 3d., from the GARDENERS' MAGAZINE Office, 148, 149, Aldersgate Street, E.C. The hellebore wash is made by mixing one ounce of freshly-ground hellebore and two ounces of flour with a little water, and when the whole is worked into a perfect paste, then add three gallons of water. Keep stirred, and apply in the form of a fine spray for sawflies, slugworms, and other leaf-eating pests.

DESTRUCTION OF VERMIN. — Most gardens are pestered with Rats and Mice. Every effort should be made at this time of the year to exterminate them before seeds are sown. Danysz Virus is first rate stuff for killing these vermin. Single tube, 2s.; three tubes, 5s. Post free from DANYSZ VIRUS LTD., 52, Leadenhall Street, Garden Dept., London, E.C.—[Advt.]

NAMES OF PLANTS.

M. M., Bristol.—Cypripedium Spicerianum.

T. S. B., Warwick.— 1, Odontoglossum gloriosum; 2, Cypripedium Lathamianum; 3, Lælia anceps.

O. W., Northampton.—1, Eupatorium ianthinum; 2, Veronica Traversi; 3, Cupressus macrocarpa.

D. E. J., Loughborough.—1, Selaginella Kraussiana; 2, Ophiopogon Jaburan; 3, Dracæna congesta; 4, Sparmannia africana; 5, Adiantum caudatum.

The Ten-petalled Sunflower (Helianthus decapetalus) — Although it has some decided drawbacks or defects, the ten-petalled sunflower, known, by the way, in its native homes as the thin-leaved or wild sunflower, is yet a plant of some degree of merit. For those who can give it a place in the wild garden or some spare corner in the garden where it will not encroach upon other flowers, it will be found most useful, and to them will be a plant of considerable value, inasmuch as it will give plenty of flowers, and will require the minimum of attention. It is a capital plant for those who have a bit of dry and poor soil in a very sunny place, as there it will flourish, although it will not grow so rampant as in moister places, and will yield a greater number of its clear yellow flowers. I am recommending for it a dry place, although in its native habitats it seeks moist woods and the sides of streams, but with us it blooms more profusely in the dry positions. It is said to grow from a foot to three feet high in the United States, but with us it is taller, and from three to five feet is what it generally attains. A useful little perennial sunflower is this, and but for its fault of spreading too quickly at the roots would be still more acceptable.—S. ARNOTT.

Saxifraga sarmentosa tricolor.—A plant of great merit, and in many ways suitable for indoor decoration, is the beautiful "tricolor" form of the old Saxifraga sarmentosa. It is easy to increase by reason of the number of small plants borne upon the extremities of the thread-like runners. These, when pegged upon the surface of small pots filled with prepared soil, will soon form roots, and in this way no difficulty can ever be experienced in securing a good stock. It is not advisable to keep plants of more than a year old unless for raising fresh stock, or for filling baskets, as the leaf-colouring reaches its highest development in young plants, and if these are grown in pots of 2½ inches in diameter, they will be found of greater service than those in larger pots. Suspended plants of this saxifraga are objects of interest and beauty during winter. They should be in rustic pans or wire baskets early in August, transferring them to the greenhouse at once, and selecting a position where the baby plants produced upon the runners will be safe from being broken or in any way damaged by accident.—THOMAS SMITH.

Selections of Fruits. — In the event of having to plant new peach trees to replace worn-out ones, or for new houses, select those varieties that will come on successively, such as Hale's Early, Gross Mignonne, Dymond, and Royal George for an early house. Violette Hâtive and Noblesse and Barrington are fine peaches of good flavour. A selection of nectarines would be Early Rivers, Cardinal, Lord Napier, Violette Hâtive, Humboldt, Pine Apple, and Spencer. These ripen in the order named. Good figs for pot culture are Bourjassotte Grise, Brown Turkey, Negro Largo, Pingo de Mel, and Violette de Bordeaux. Good plums for pots, or for orchard houses are Angelina Burdett, Bryanston Green Gage, Denniston's Superb, Golden Transparent Gage, Jefferson, Reine Claude de Bavay, Reine Claude Violette, Kirke's, and Green Gage. These do very well under glass, and much better than most people think, and the grower is always certain of a crop, as he has not the spring frosts to contend with. Grand crops of these, together with pears and cherries, can be grown in cool houses, say, with one pipe running round to guard against frost.—W. A. COOK, Leonardslee Gardens.

CATALOGUES RECEIVED.

MESSRS. GEORGE BUNYARD AND CO., MAIDSTONE.—Catalogue of vegetable and flower seeds. An excellent list containing all the best of the vegetables and flowering plants. and is of special interest for the numerous fine types that have been introduced by the firm. The catalogue is freely illustrated, and the illustrations will be found excellent aids in making selections.

GILBERT AND SON, DYKE, BOURNE.—A neat list of seeds, in which sweet peas are specialised.

COOPER, TABER, AND CO., LIM., 90-92, SOUTHWARK STREET, S.E.—An excellent wholesale catalogue of flower and vegetable seeds, illustrated with portraits of novelties and views of the firm's seed farms at Witham.

FISHER, SON, AND SIBRAY, LIM., HANDSWORTH, SHEFFIELD.—This large catalogue of seeds contains a good list of vegetable and flower novelties. Also a useful catalogue of trees and shrubs.

J. R. PEARSON AND SONS, LOWDHAM, NOTTS.—This very attractive catalogue contains some unusually fine illustrations of annuals, etc.

J. M. THORBURN AND CO., BARCLAY STREET, NEW YORK, U.S.A.—A handy little catalogue of American seeds, issued for the European wholesale trade only.

PENNICK AND CO., DELGANY NURSERIES, CO. WICKLOW.—A very comprehensive catalogue of hardy trees and shrubs, fruit trees, and herbaceous plants; illustrated.

LITTLE AND BALLANTYNE, CARLISLE.—A catalogue of flower and vegetable seeds, including novelties for the year.

OIL, GAS, OR FUEL

V1 FLUID

THE WINTER SPRAY FLUID.

THE PRIORY GARDENS, ROEHAMPTON, S.W. November 14th, 1908.

Sirs,—I purchased 2 gallons of V1 and sprayed about half the trees under my charge here, doing the other half with another preparation. I have much pleasure in saying that V1 has exceeded my expectations; the trees kept clean all the Summer, with the exception of a slight attack of Green Fly upon the young shoots of some plum trees, which was soon got rid of by an application of V2 Fluid. I have no hesitation in saying that if your two Fluids are as effectual in the future as they have been here this season, no one need have dirty trees or maggoty and misshapen fruits.

Yours respectfully, **D. CAMPBELL.**

V1 FLUID IS EASY TO MIX AND EASY TO APPLY.

1 Gallon of Fluid makes 100 Gallons of Spray Mixture.

Prices and Descriptive Booklet on application to:—

Wm. COOPER & NEPHEWS, Berkhamsted.

Printed and Published by W. H. & L. COLLINGRIDGE, City Press, 148 & 149, Aldersgate St., London, E.C., and sold by all Newsagents, and at all Railway Bookstalls.

SOW NOW UNDER GLASS.
SUTTON'S SELECTED AILSA CRAIG ONION. Per packet, 2s. 6d., post free.
Mr. W. Turnham, gardener to W. H. Barber, Esq., writes: "I have grown your Selected Ailsa Craig Onion for several years, but never before had them to such perfection as this season, and I consider this to be the finest type of Onion in cultivation. The two heaviest bulbs weighed 8lbs., 12 heaviest bulbs 42½lbs., and the 100 heaviest bulbs 300lbs. The 600 bulbs in the bed weighed 1,405lbs.—an average of 2lbs. 5oz. per bulb."

SUTTON AND SONS, THE KING'S SEEDSMEN, READING.

NOW IS THE TIME TO PLANT (the best time of the whole year) KELWAY'S BEAUTIFUL BLUE DELPHINIUMS. Hardy, and flourishing in every garden, they are the STATELIEST of PERENNIAL PLANTS for borders or beds; these celebrated improvements are invaluable for their introduction of that precious colour—blue—in masses to the garden. KELWAY and SON developed this race, and they should be procured direct from the Royal Horticulturists, Langport.

KELWAY'S IMPROVED DELPHINIUMS are now ready, strong plants, in choice named selections. Collection "B," 15s. per doz. Collection "D," 42s. per doz. Delivery free for remittance with order. KELWAY and SON, The Royal Horticulturists, Langport, Somerset.

FRANCO-BRITISH EXHIBITION, 1908. ONE of the ONLY THREE Gold Medals (or Higher Awards) (open to the whole world for permanent exhibits) awarded by the International Jury, and confirmed by the Governing Council was awarded to Kelway and Son; vide the AUTHORISED LIST published in the Press.—KELWAY and SON, Langport, Somerset.

FOR PRESENT PLANTING.

TO-DAY! AND FOR YEARS AND YEARS PAST the XL ALL Specialities are and have been the best on the market. Where is the Gardener who does not pin his faith to one or the other of these celebrated Insecticides or Fertilisers? XL ALL FERTILISER has pleased all who have used it this season. The Sales of XL ALL FUMIGATOR prove that it is more popular than ever. XL ALL LIQUID NICOTINE INSECTICIDE is always spoken of by gardeners and growers as the most deadly to Mealy Bug, Thrip, etc. XL ALL WINTER WASH for dormant Trees acts like magic, clearing the Trees and Bushes of all Insects' Eggs, Moss, and Fungoid Growths. XL ALL LAWN SAND, a weed eradicator and fertiliser for weedy and poor lawns. XL ALL WEED KILLER used once a year "No weeds can live." Please ask your Nurseryman, Seedsman, or Florist for a copy of my small pink list, giving particulars of these and many other XL ALL Preparations, which can be obtained from the Horticultural Trade throughout the World. G. H. RICHARDS, Manufacturer and Patentee, 234 Borough High Street, London, S.E.

NOTES OF THE WEEK.

Fog.

Fog, roughly speaking, may be defined as a volume of watery vapour resting either upon the surface of the sea or that of the land, and determined by a difference of temperature between the earth or the water and that of the air adjacent thereto. Thus, a cold stratum of air resting on a warmer sea, or a warm stratum resting on colder water or similar land conditions, is, under calm conditions, almost inevitably bound to breed a fog or mist of greater or less density owing to the condensation of otherwise invisible aqueous vapour in the air due to the chill involved. Aerial clouds are precisely akin in their nature, as is easily seen in hilly parts of the country in the early morning, masses of mist or fog then resting on the ground with precisely the same billowy outlines as the clouds floating high above, the difference being solely one of position. Fogs of this class, which may literally be termed fogs pure and simple, are in no way deleterious, vegetation is, indeed, benefited by their presence, since the water deposited from them is pure, and they act as a sort of blanket by reducing radiation, and, as a consequence, modifying the effects of frost. In the vicinity of large towns or cities, and especially manufacturing ones, where considerable smoke and other deleterious vapours are thrown into the air from a myriad chimneys and shafts, very different conditions prevail. The aqueous particles, rendered visible by condensation for the reasons above given, are here associated with both poisonous gases and poisonous substances. These, in any case, the gases especially, are, even under dry conditions, detrimental to plant life, but under wet ones, such as condensed mist provides, they become ten times more so, since the water in which they are partly dissolved adheres to the foliage and consequently penetrates the tissues at the same time that it causes the undissolved impurities, soot, etc., to adhere and clog the stomata, or what may be termed the breathing pores of the plants, so that they are not merely poisoned, but suffocated. That this is the case is easily seen, say in a London garden after a typical November fog, when any soft green foliage will be found to be not merely blackened and destroyed by the poisonous action of absorbed gases, but fouled with adherent dirt deposited from the air. Apart, too, from the merely condensing action of cold upon suspended watery vapour, it has been demonstrated that the suspended particles of soot, dust, etc., present in smoky air, themselves induce condensation, forming a sort of nucleus and often creating a dry fog, and it is this class of fog which is so apt to accumulate in a dead calm in and around large towns, and owing to this association, creates those dense, "pea-soup" fogs which we never behold in truly rural districts where the inducing factor of dirt is absent. Undoubtedly the most poisonous element in urban fogs is the sulphurous acid gas given off by coal during its combustion. To plant life this is most deadly, and the destruction which we see in our gardens, and even in our conservatories, after an attack of dingy brown fog is mainly due to this poison, introduced either in solution or absorbed in the gaseous state through the pores of the leaves. Remedy there is practically none, since under such circumstances the air is pervaded with the deleterious matter. Fortunately, the worst of these aerial inflictions occur late in the autumn or in the winter when vegetation is largely at rest, but there is little doubt that many evergreen plants, alpines especially, suffer terribly, and are often killed outright from the effects of such visitations. Happily, too, much is being done in these days, both by legal regulations and the application of new inventions to the thorough combustion of fuel to reduce these evils, but much still remains to be done before the "London particular," of which, by the way, London by no means has a monopoly, since every big city is its rival to some extent, is transformed into harmless cloud of the snowy rural type.

MR. GEORGE WOODGATE.

Mr. George Woodgate, whose portrait is given herewith, has long held a foremost position amongst the leading gardeners of the United Kingdom, and is held in the highest estimation by his many friends engaged in garden management. Commencing his career under his father, who was gardener at Stanstead House, Godstone, Mr. Woodgate served in some of the best establishments in this country, and in passing through them laid the foundation of his thorough acquaintance with the art of gardening, which has contributed so materially to his success in after life. Mr. Woodgate's first charge was at Heathfield, Sydenham Hill, where he remained until his appointment as head gardener at Warren House, Kingston Hill, where he specially distinguished himself in the management of the fine gardens associated with that residence. Mr. Woodgate continued in charge of the Warren House gardens until 1894, when, on the death of Lady Wolverton, the property was sold, and he received his present appointment as head gardener at Roileston Hall, Burton-on-Trent, the residence of Sir Oswald Mosley, Bart. While busily engaged in bringing his remarkable administrative ability and skill to bear upon the management of the gardens under his charge, and closely studying the wishes and requirements of his employers, Mr. Woodgate has not overlooked his responsibilities as a citizen. We have evidence of this in the fact that from 1885 to 1894 he was honorary secretary of the Kingston Chrysanthemum Society, which was then one of the leading organisations associated with the cult of the chrysanthemum, and here he achieved much success. During the past three years he has filled the office of churchwarden at his parish church; from 1885 he has been a subscriber to the Gardeners' Royal Benevolent Institution, and he has subscribed to the Royal Gardeners' Orphan Fund from the foundation of that charity. We might add that Mr. Woodgate has achieved considerable success as an exhibitor, and in this direction has shown that he is essentially what is commonly known as an "all round" cultivator.

Veitch Memorial Prizes.—At a recent meeting of the Veitch Memorial Trustees it was decided to offer gold medals to the Rev. W. Wilks, secretary of the Royal Horticultural Society, and Mr. W. Marshall, V.M.H., chairman of the Floral Committee, in recognition of the valuable services they have rendered to horticulture. The following prizes of a medal and £5 each were also offered: To the R.H.S., at their Temple Show, for the best group of orchids, not exceeding 75 feet, staged by an amateur who has never taken a medal at either the Temple or Holland House Flower Shows; to the Cardiff and County Horticultural Society, for the best amateur exhibit of twelve distinct varieties of hardy flowering shrubs (cut): and to the National Rose Society for competition at their exhibition in July next. At the same meeting Mr. J. Douglas, of Great Bookham, was elected a trustee, in the place of the late Mr. G. Nicholson.

R.H.S. Report.—The report of the Council of the Royal Horticultural Society that will be submitted to the Fellows assembled in annual meeting on Tuesday next is, as usual, of a highly satisfactory character, affording, as it does, evidence of the continued growth of the society in popularity and usefulness. The Council describe the past year as one "of quiet, steady progress," and in this description they certainly do not overstate the case. The Wisley Gardens, we learn, continue to increase in favour with Fellows, and all branches of work that is being carried on therein are showing good results. The new laboratory is proving of great assistance to the educational work, and the result of the first year's work of the students has been highly satisfactory. In the general examination in horticulture the scholarship of £25 a year for two years, offered by the Gardeners' Company, was won by Mr. Perry, one of the Wisley students. The number of visitors to the gardens admitted by Fellows' tickets during 1908 amounted to nearly 11,000, or an increase of over 2,000, as compared with 1907. Last year deputations from the society attended Truro, York, and Newcastle, and invitations have been accepted to send this year deputations to Birmingham and Cardiff. The exhibitions held in the gardens of the Inner Temple and Holland House were, as our readers have been informed, eminently successful, and arrangements have been made for again holding these gatherings this year. The Colonial fruit show in November last was also successful. Reference is made in the report to the omission of the autumn fruit from this year's programme and to the offering of prizes for fruits and vegetables at the fortnightly meetings. With reference to the society's "Journal," it is mentioned that Mr. G. S. Saunders, F.L.S., had to retire from the post of editor owing to ill-health, and that Mr. F. J. Chittenden had been appointed his successor; it is further stated that in future it will be issued quarterly. With a view to the proper recognition of skilful scientific work amongst plants a new certificate has been created and this will be known as "The Certificate of Appreciation." There was a substantial increase in the number of Fellows during the year. The loss by death was 130, representing an income of £171 3s., and the loss by resignation 646 of Fellows, Associates, and affiliated societies, representing an income of £782 5s. The total loss in numbers was 646, and in income £953. The number of Fellows, etc., elected was 1,283, representing an income of £1,961 8s. Therefore the numerical increase was 507, and the net increase in income £1,008.

Kew Gardens.—At the next meeting of the London Branch of the British Gardeners' Association, to be held at Carr's Restaurant, Strand, W.C., at 7.30 p.m., on Thursday, February 11, Mr. Chas. H. Curtis will give a lecture on "Kew Gardens; Their History and Attractions," and the lecture will be fully illustrated by a large number of lantern slides. Professional gardeners, whether members of the association or not, are invited to attend.

Potato Exports to America.—English-grown potatoes are highly appreciated on the other side of the Atlantic, and as the result of this appreciation they are annually shipped to the United States in considerable quantities. This season the exports are larger than usual, owing probably to the low prices ruling, and of these the larger proportion is being sent from Holbeach, the centre of one of the most important of the potato-growing districts in Lincolnshire. From this centre about 1,000 tons are despatched weekly to America. The price paid to the farmers is about £1 15s. per ton, and in addition to the cost of transit the potatoes have to bear a duty of £1 17s. 6d. per ton.

Flowers at Olympia.—On the occasion of the International Horse Show at Olympia in June next, the principal feature of the decorations will be the floral display. In connection with the floral decorations we are informed that "a floral artist" has visited Bruges and Ghent for the purpose of selecting choice trees and shrubs and various flowering plants. Why visit Belgium, or other Continental country, to purchase such things, when they can be obtained in abundance, and of the highest quality, in British nurseries?

Seeds.—At the annual meeting of the Royal Microscopical Society, held the other evening, Lord Avebury, the retiring president, gave an address on "Seeds," with special reference to British plants. In his opening remarks Lord Avebury said that annually there were enormous losses of seeds of plants growing under natural conditions. Large proportions of them were eaten by animals or failed to secure a suitable site for germination. Of those which did germinate many were crowded out. The greater the chance against maturity the larger the number of seeds must the plant produce, and, as a rule, the smaller they would be in size. On the other hand, the greater the chance of arriving at maturity the smaller was the number of seeds necessary, and in such cases it was an advantage that the individual seeds should be large. Parasitic plants generally produced a large number of very small seeds. There were seeds or fruits with wings, which were carried by the wind; those with feathery appendages, which were carried by wind, and sometimes floated by water; those in capsules, which opened at the top and allowed the seeds to be jerked out; those with hooks, which were carried by animals; those which were eaten and thus carried by animals; and those which were thrown considerable distances by the plants. Some seeds mimicked small insects, and were no doubt picked up and carried a distance by the birds before the mistake was discovered. The protection of seeds was of the utmost importance to the plant, all the more so as their nutritious properties rendered them specially tempting to animals and to vegetable parasites. Seeds and fruits which were often protected by hardness or bitterness when immature became sugary, well-flavoured, and sweet-scented when ripe, and when their dispersal was to be effected by animals. In other cases protection was afforded by thick, hard envelopes which did not open until the seeds were ripe.

R.H.S. Finances.—The income of the Royal Horticultural Society in 1908 was £21,915 2s. 7d., and the expenditure £14,048 2s. 7d., those figures representing a profit on the year's work of £7,867. The investments of the society now amount to £33,986 7s. 8d., of the approximate value of £31,623 16s.

Bulb Show at Hillegom.—We are informed that in April next an exhibition of Dutch bulbous flowers will be held at Hillegom, one of the centres of bulb culture in Holland. The exhibition will include a permanent display in the open, so arranged as to afford object lessons in the use of bulbs in the flower garden, and temporary shows in tents. The opening of the exhibition has been fixed for April 8, and will continue until the end of the first week in May.

Famous Cornish Gardens.—The second part of the illustrated account of some of the more noteworthy Cornish gardens will be given in our next issue.

Bermuda Lilies.—The cultivation of lilies for the production of bulbs for export forms an industry of some importance in Bermuda, but for several years past the culture has been under a cloud. This cloud, we learn on good authority, is rapidly passing away, and there is now a good prospect of the industry resuming its once flourishing conditions. One of the greatest hindrances to the full recovery of the industry is, according to the report of the Bermuda Board of Agriculture, the unrestricted export of bulbs not true to type. This is stated to hamper the sale of selected stock, and to keep prices low. The superintendent of the Bermuda public gardens states that the practice which has obtained of exporting as Lilium Harrisi bulbs that are not of that lily has reduced the value of the lily bulb industry by 80 per cent. Several of the larger of the growers have during the past two or three years carefully weeded out during the season of growth plants of L. longiflorum and hybrids, and have thereby obtained true stocks of L. Harrisi. Last year 6,399 cases of bulbs were exported from Bermuda.

CHRYSANTHEMUMS IN SCOTLAND.

This heading may at the first glance cause some perplexity as to what is meant, but I shall soon be able to show to what I refer.

For some years I have observed how well Scotch cultivators succeed with certain varieties, while in England these same sorts are hardly known, at least not in the handsome manner in which they are presented at the Scottish shows. With a view of assisting especially the young Scotch growers, I will direct attention to a few of the more prominent varieties that were seen at the Edinburgh show in November last. Mrs. A. G. Pirie, a sport from Mdme. Cadbury, is a particularly pleasing yellow-flowered variety, unique, perhaps, in the way that two shades of yellow are made so distinct. The surface of the broad florets is a rich golden yellow, with a pale yellow reverse. The blooms are not so large as some, but in quality they are good.

Victoria and Albert is seldom named in English catalogues, and but rarely seen at shows; in fact, I do not remember seeing a single bloom at any English show this season, but at Edinburgh it was staged in the three great classes and in such condition as to obtain 10 points out of a possible 12. In colour the blooms are a deep rich yellow, especially admirably built, and well-filled in the centre.

W. Ring.—In England I saw but one good bloom during the season, but in Scotland it was well shown. The golden buff florets were loosely incurving, making a bold, handsome blossom.

Marquise V. Venosta.—The blooms of this variety were exceptionally well built, white and very fresh in appearance.

Lady Conyers.—In England this variety is seldom seen, being one of the worn-out varieties. Here it is a favourite and is staged in such condition as to ensure the blooms obtaining as many as nine points.

Mrs. G. Mileham was at Edinburgh very rich in colour, the wide, flat, naturally reflexing florets exposing the rich surface fully.

Miss R. Stoop is another white-flowered variety almost a stranger in England. In the North it is usually well shown.

Splendour was shown at Edinburgh so well as to give one the impression that as a Scotch variety it will last a considerable time.

Elsie Fulton has long been a favourite, the florets are usually so massive and so pure in colour.

President Viger displays fully its deep rosy-purple tint as to render it a conspicuous bloom in the majority of stands.

Mrs. Eric Crossley, light golden yellow, is another favourite with Scotch growers, and with good reason, the blooms are full and shapely.

Mons. L. Thorne reminds one of a loosely formed flower of Bessie Godfrey with longer petals.

Florence Penford succeeds remarkably well in the North. The blooms are deeply built, measure as much as 9 inches in diameter, and finish well. The chrome-yellow colour was richly flushed with fawn.

Algernon Davis nowhere carries the rich bronze tint on the extra broad florets that we see in Scotland. The cooler conditions apparently develop more deeply the colour tints. As many as 10½ points were awarded this variety. The florets measured slightly over half an inch in width.

Of the ordinary varieties Reginald Vallis, Mrs. F. W. Vallis, F. S. Vallis, J. H. Silsbury, Lady Talbot, Mrs. A. T. Miller, Bessie Godfrey, Edith Jameson, Mrs. C. Penford, Melchet Beauty, Mdme. P. Radaelli, and its yellow sport Mdme. G. Rivol well retain their popularity in the North.

A Southerner.

ALPINE PHLOXES, OR MOSS PINKS.

The name of phlox is so intimately associated in our minds with the brightly-coloured border plants which flower during summer and autumn that there is some fear of our ignoring the merits of an equally beautiful section of this important genus, namely, those species and varieties which, for the most part, flower in spring. These dwarf, creeping, or as we may for the present regard them, alpine phloxes, share with aubrietias an equal freedom in growth, floriferousness, and ease in propagation, and they adapt themselves to various positions and uses. Nor do they readily deteriorate or exact but a minimum of labour and attention throughout the year.

Their beauty lies in the delicate colours and texture of the petals, accentuated by the fine pencilling which constitutes what we term the "eye." They are best employed in masses from a foot to a yard across, preferably on some sloping bank, or in a position where they can be allowed to drape the surface of a rock. They are such good amateur's plants that it is difficult to conceive of them being ever employed to ill-effect, for, being evergreen, their foliage in winter clothes the ground with life, and in spring and early summer they transform the dullest surroundings in the garden into pictures of greatest beauty.

A species which has given a great number of varieties of the highest excellence is Phlox subulata. It is an evergreen, having long trailing stems densely clothed with close-set, pointed leaves, characters which are constant in all its offspring. It prefers a well-drained soil, and the best results are obtained in that which is moderately rich in plant food. The type has purple flowers. The best varieties of P. subulata include Nelsoni, white, blue eye; Lilacina, pale lavender, similar to G. F. Wilson; Atro-lilacina, deep lavender; Brightness, deep rose, scarlet eye; Daisy Hill, deep rose, crimson zone; Sprite, rose-pink, carmine eye; all flower in May and June.

Of other alpine species, Phlox reptans is worthy of a place; it differs from P. subu-

LÆLIO-CATTLEYA FELICIA.

Flowers blush and crimson-purple. F.C.C., R.H.S., January 26. Messrs. Charlesworth and Co., Haywards Heath.

lata in having obovate, spathulate leaves, and the stems root at every joint; the flowers are violet-purple. I find it succeeds admirably in quite indifferent soil, and it is one that is reliable in flowering. Phlox verna has creeping stems, like P. subulata, broad leaves like P. reptans, and flowers of a very bright shade of pink; it is especially desirable for the rock garden.

Phlox divaricata is larger and coarser in growth than P. subulata, which it resembles in a general way; it is equally desirable as a garden plant, and is even less fastidious as to soil. The flowers are pale lilac, emerging into full lavender in the variety canadense. Neither of these forms can approach in beauty the variety named Laphami (Perry's variety), than which there is no finer subject in the garden during May and June, as it flowers with prodigal freedom. The individual blooms are very large, and are borne in big heads upon wiry stems some 15 inches in height, while the colour is a lovely shade of lavender. During the summer of 1907 I employed it as the dominant colour in a garden scheme where the flowers were restricted to lavender and blue, and it produced a novel effect, lasting quite four months in flower. The growth is never too dense, and thus it admits of being interplanted with other subjects which carry on the flowering season till autumn.

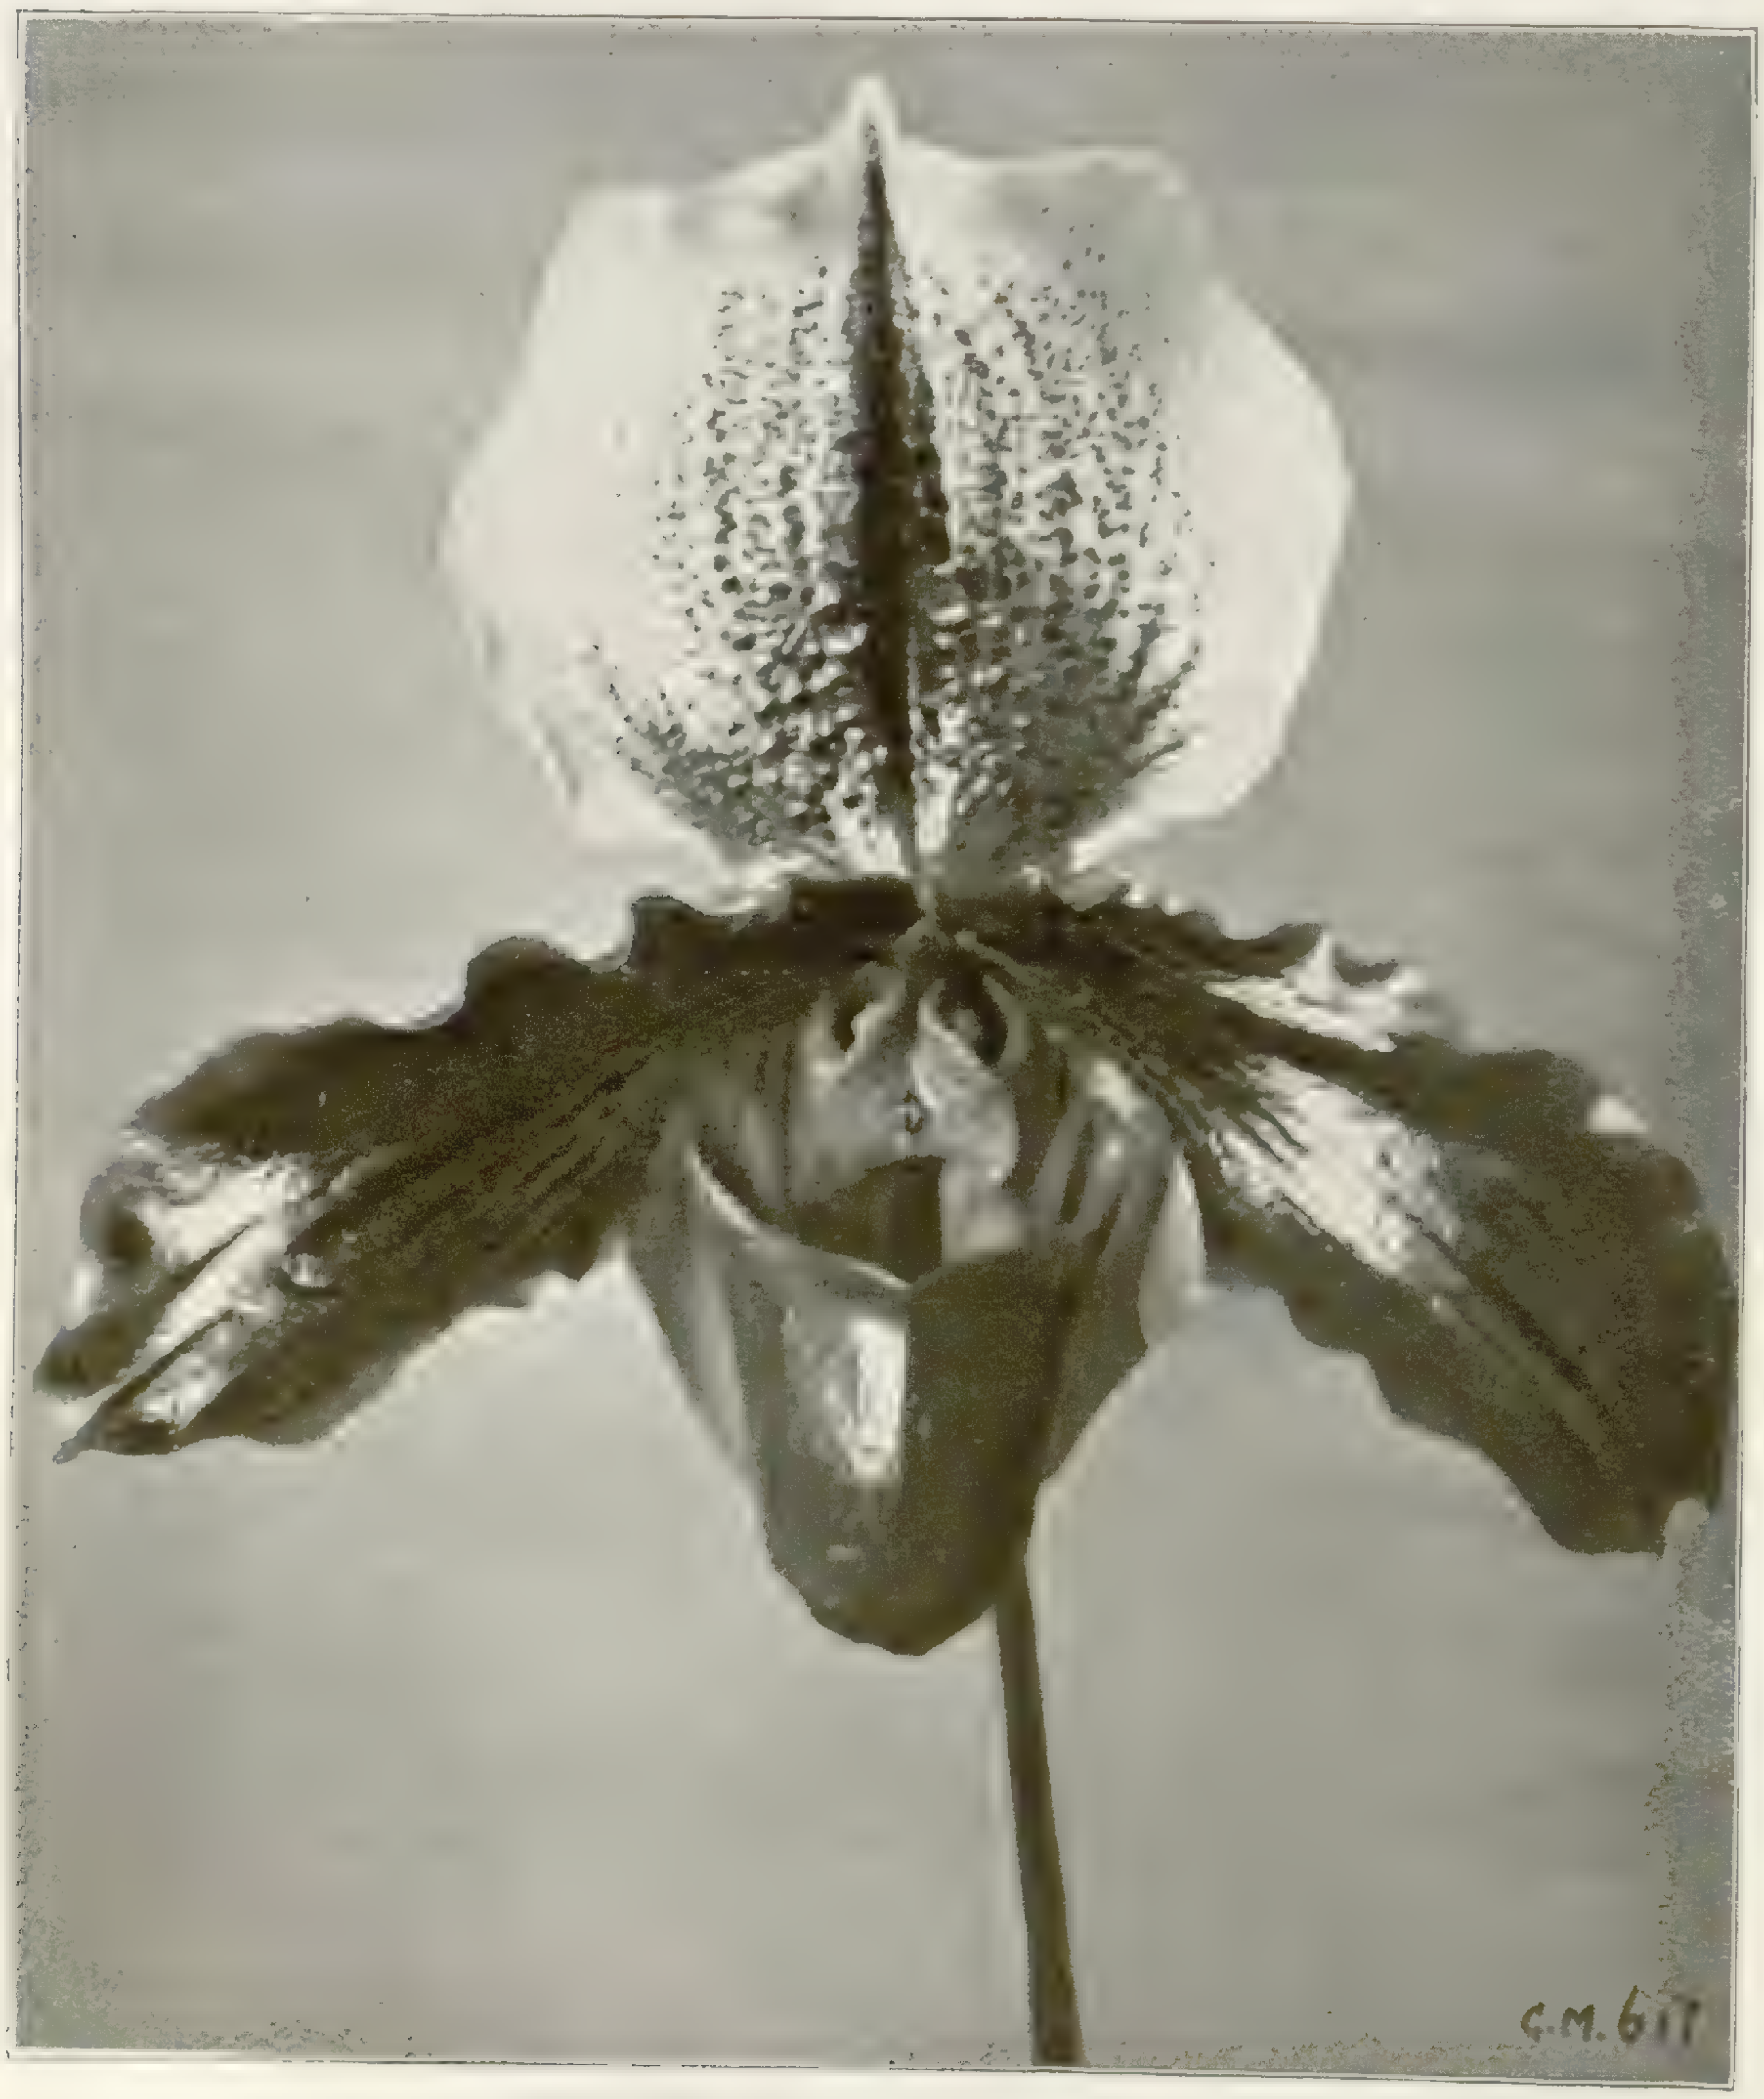
Propagation of all these phloxes is comparatively easy, the stems of the mossy section, if pressed into the soil and covered, will soon produce roots, or cuttings taken during July and inserted in small pots containing sandy soil will yield the same result. P. Laphami will strike from cuttings at any season if treated in like manner, and it is a good subject to grow in pots to bloom in the greenhouse during early spring. **Thomas Smith.**

Walmsgate Gardens.

NEW PLANTS, ETC.

CYPRIPEDIUM OUR QUEEN.

This very bold and finely coloured cypripedium is derived from a dark form of C. Leeanum, crossed with C. Stevensi. The dorsal sepal has a white ground heavily marked with bright purple, the spottings being confluent down the centre. The broad, wavy petals are yellow-green, brightly shaded with purple. The pale green lip serves to heighten the colouring of the other organs. A.M., R.H.S., January 26. Mr. W. Stevens, gardener to W. Thompson, Esq., Walton Grange, Stone, Staffs.



CYPRIPEDIUM OUR QUEEN.
Flowers white, purple, and green. A.M., R. H.S., January 26. Mr. W. Thompson, Walton Grange, Stone, Staffs.

CYPRIPEDIUM EARL OF TANKERVILLE.

This is a very roundly formed cypripedium: indeed it is almost too formal, and a little extension of the broad, rounded, white dorsal sepal would have been an improvement. The dorsal sepal has numerous dark purple spots that are paler towards the apex. The petals and lip are yellowish green, shaded with bright brown. The parents of this fine variety are C. exul and C. nitens Sanders' var.

A.M., R.H.S., January 26. Mr. H. Alexander, orchid grower to Lieut.-Colonel Holford, Westonbirt, Gloucester.

SOPHRO-LÆLIO-CATTLEYA MARATHON VAR. VESUVIUS.

This very brilliant hybrid is the result of crossing Sophro-lælia Psyche with Cattleya Empress Frederick. The flowers are of moderate size and the labellum is very prettily waved. The sepals and petals are rich rose-red, flushed with crimson, and with a yellow shading down the centre. The lip is rose-red, heavily shaded with ruby-crimson, and has a yellow base. A striking novelty. F.C.C., R.H.S., January 26. Messrs. Charlesworth and Co., Haywards Heath.

LÆLIO-CATTLEYA FELICIA.

A fine bold hybrid, reminding one of L.-c. callistoglossa. The parents are L.-c. Haroldiana and C. Trianæ. The sepals and petals are blush coloured, and the very large, broad lip is of a brilliant and deep shade of crimson-purple. F.C.C., R.H.S., January 26. Messrs. Charlesworth and Co., Haywards Heath.

CHRYSANTHEMUM GOLDEN SUNSET.

A remarkably useful and effective late decorative chrysanthemum, said to be a sport from Princess Victoria. The flowers are of medium size, rich golden-yellow, with reflexing florets, and carried on good stems. A.M., R.H.S., January 26. Messrs. Robinson and Headey, Dunstable.

CYPRIPEDIUM EURYADES NEW HALL HEY VAR.

A handsome hybrid resulting from C. Leeanum superbum, crossed with C. Boxalli, but, as shown, it was rather too narrow at the base of the dorsal sepal. The latter is white, marked with purple, and the petals and lip are yellow-green, shaded with brown and purple. A.M., R.H.S., January 26. Mr. J. Forster Alcock, Exhims, Northchurch.

CLERODENDRON UGANDENSE.

A strikingly handsome plant, growing from 2ft. to 3ft. high, and bearing loose racemes of beautiful blue flowers. The anterior lobe of the corolla is bright violet-blue, and the other segments pale blue, while the filaments are purplish blue. This species flowers in autumn, it grows freely in an intermediate house, is easily propagated from cuttings of young shoots, and so promises to become an extremely useful decorative plant for warm conservatories. Bot. Mag., t. 8,235.

ANGADENIA NITIDA.

Though not likely to oust old favourites, there seems to be room in tropical houses for this South American climber. It grows freely in a stove, and in July bears racemes of yellow dipladenia-like blooms. Bot. Mag., t. 8,233.

LONICERA GIRALDI.

A new honeysuckle from China. It is of shrubby habit and bears hirsute, lanceolate leaves, and short terminal panicles of red flowers that are rendered the more effective by the exserted yellow stamens. The species was introduced by Mons. Maurice L. de Vilmorin, who obtained seeds from Szechuan in 1899, and flowered plants at Verrieres in 19 Bot. Mag., t. 8,236.

ENCEPHALARTOS BARTERI.

An interesting cycad from West Tropical Africa, where it is known as the Ghost Palm. It appears to be not very plentiful, and under cultivation it is by no means a success, plants rarely surviving long even under the most careful treatment at Kew. The species is short-stemmed, and its bright green leaves, 3½ft. to 5½ft. long, bear about 80 pairs of sharply pointed, serrated leaflets. Bot. Mag., t. 8,232.

CYTISUS DECUMBENS.

A small-growing species having a trailing habit, and producing a profusion of bright yellow flowers in May. It is well adapted for trailing over broad ledges in the rock garden, and for carpeting beds occupied by [illegible] growing plants. This charming broom is a native of Southern Europe. Bot. Mag., t. 8230.

PENCARROW: GARDEN FRONT AND FLOWER GARDEN.

SOME MORE CORNISH GARDENS—I.

So many kind things were said and written about the descriptions of Cornish gardens that have already appeared in these pages that the task of reviewing another set becomes a pleasant one. On a former occasion the Isles of Scilly formed one text, and, later, Falmouth was the centre of operations. The present set covers a wider range, and shows that while Cornwall is very mild and moist throughout, there is a considerable difference between what is possible at Pencarrow and Prideaux Place, in the north, and Bosahan and Trewidden in the south.

Pencarrow.

When, in the small hours of the morning, I changed at Liskeard for Bodmin, the rain was falling heavily, and the prospects of a fine day for visiting Pencarrow were extremely small. At Bodmin the prospects were still dismal, and but for the company of Mr. A. C. Bartlett, an old Kewite, who met me, the three and a-half miles drive, northward, to Pencarrow, would have sufficed to damp one's ardour considerably.

Pencarrow is a large estate belonging to Mrs. Ford, who has a very great affection for her garden and woodlands, and for the fine trees that abound. The trees are the outstanding feature of the Pencarrow estate, and conifers are especially fine and abundant. The estate has belonged to the Molesworth family ever since the time of Queen Elizabeth, and the late Sir William Molesworth, Bart., one-time Colonial Secretary, lived here for a long number of years, and did a great deal of planting. The long white, comfortable-looking house occupies rather low ground, and is admirably sheltered by the higher ground around and by the belts of fine trees found at almost every point. The flower garden is a sunken one and surrounded by a light ornamental iron fence, and each gateway has stone pillars surmounted by large flower-filled vases. The general design is a formal one, but, as the illustration shows, the planting is not of a strictly formal character. Irish yews and retinosporas are noticeable, and the former are numerous on the far side where the rock garden commences. Yuccas, cordylines, Trachycarpus excelsa, and pampas grass are subjects largely used in this garden, but there are roses as well, and in the summer time begonias and pelargoniums fill the beds around the central fountain. Hard by are several eucalypti, notably E. Gunni and E. globulus. The last-named has flowered at Pencarrow; it sometimes suffers from wind, but scarcely ever from frost.

The rockery is distinctly not a rock garden. It is 120 yards long and was made by Sir William Molesworth, and was a great hobby of his. He was a kindly man and so well liked in the district that when the neighbouring farmers came to know of his hobby they carted the huge stones from nine or ten miles away right to the spot, and, though they did it freely for love of the squire, it is said the flower garden and rockery cost him £20,000. The rockery is more interesting than beautiful. It affords a home for a large collection of dwarf shrubs and for the hardier kinds of alpines; it also provides a cool and quiet retreat, for, passing between two huge boulders, one finds a tiny path that leads to a rocky summer-house, where, sheltered by the trees behind, and screened by the piled-up plant-clothed rockwork in front, one could pass many a summer afternoon in quiet comfort.

How can one describe the grounds and woods of Pencarrow? The long drives are magnificent and mostly of greensward in place of road-metal. One such drive or avenue, composed partly of Araucaria imbricata, is one and one-third miles in length. The woodland valley that gradually opens out before you as you pass away southwards from the flower garden is beautiful as Nature made it, and Nature has been assisted by the various holders of the estate, and later by Mr. A. C. Bartlett, Mrs. Ford's young and enthusiastic head gardener. The little stream runs very irregularly between the sharply sloping banks, amid ferns and under fine trees. Magnolias and rhododendrons, camellias and azaleas are grouped boldly here and there along the banks, and at various convenient positions rare conifers have been planted, so that the reputation of Pencarrow may be maintained for long years to come. As an example, I may notice that Widdringtonia Whytei, the Mèlanje Cedar, has been planted in several places. In one part of this valley is an opening at the end of a walk, and here are eucalypti, camellias—the latter in full flower—and hydrangeas that tell of grand effects produced in summer.

Where the banks recede somewhat opportunity has been taken to form a semi-wild and bog garden. Gunnera manicata is a great success and spreads its noble leaves around in summer time. G. scabra is also good, but it suffered a good deal in

1906-7. There is also here an unnamed gunnera sent from Chili by Mr. Elwes; it seems intermediate between G. scabra and G. manicata, it starts early into growth, lasts well, and is very hardy. Irises, arundos, bamboos in great variety, and many other moisture-loving plants are utilised here in this sheltered spot, and uncommonly well do they thrive.

Farther along is the ruin of an old fowl-house, once used for the acclimatisation of rare aquatic birds, but it is now almost hidden by two very big specimens of Trachycarpus excelsa, carrying large heads of fine leaves, and behind them is a fine Dracæna indivisa, while under all is a carpeting of the pretty Mother of Thousands (Saxifraga sarmentosa). Choice conifers, of various sizes, in the neighbourhood of this bog and wild garden, are Podocarpus excelsa, P. Totara, P. nubigena, and P. chilinus, Prumnopitys elegans, and Saxegothaea conspicua, both about 4ft. high. Here also is a tall Eucalyptus urnigera and E. coccifera; the latter, with its blue stems and three distinct forms of leaves, was coming into bloom when I saw it.

A little higher up the valley is a pond, formed by holding back the stream. It is surrounded by a wealth of rhododendrons, and in it are large groups of arum lilies. We pass a strong young Davidia involucrata, a plant everyone wants to see producing its brilliant bracts. Cephalotaxus drupacea, and a fine sugar maple, arrest attention, and from here we can see the splendid specimen of Pinus insignis that stands below; it rises 90ft. high, and is supposed to be the finest in the country. There is another specimen taller, but not finer, and this, which measured 101ft. high four years ago, Mrs. Ford helped to plant when a girl seven years of age. She is now over ninety.

[Photo: W. Rochard.

A MUSA, AND PART OF THE ROCKERY AT PENCARROW.

In spite of the rain I saw a good deal of Pencarrow, and I made far more notes than can possibly be used now. With Mr. Bartlett I walked through miles of woodlands and looked out from the northern edge of the estate upon the Cornish hills Roughtor and Brown Willy, away to the northward. We also visited the old circular encampment that occupies the highest point in the park. Here are the three ramparts and ditches, with the sides of the entrenchments crowded with old and curiously stunted oaks, and it is said that Jan Ridd, well known as the hero of Blackmore's "Lorna Doone," met and overcame the famous Cornish champion wrestler in this enclosed space.

I must conclude with the measurements of a few of the finest of the conifers at Pencarrow, and with the advice that, though it is right off the beaten track, indeed, a rather out-of-the-way place, Pencarrow, Washaway, S.O., Cornwall, should be visited by all who are keenly interested in arboriculture. The following are the heights and girths, as measured in April, 1907, and kindly supplied by Mr. Bartlett: Abies firma, 49ft. by 6ft. 5in.; A. Veitchi, 40ft. by 3ft. 10in.; A. cephalonica, 70ft. by 11ft.; Picea polita, 34ft. by 3ft. 4in.; P. Alcockiana, 25ft. by 2ft. 3in.; P. Morinda, 60ft. by 6ft.; Pinus Russelliana, 49ft. by 5ft. 9in.; P. Montezumæ, 53ft. by 9ft.; P. Banksiana, 35ft. by 3ft. 1in.; P. insignis, 91ft. by 14ft. 9in.; Cupressus torulosa, 42ft. by 5ft.; C. t. majestica, 32ft.; C. obtusa, 24ft.; C. nootkatensis, 38ft.; Cryptomeria japonica, 65ft. by 7ft. 10in.; C. elegans, 36ft.; Cunninghamia sinensis, 48ft. by 4ft. 9in.; Fitzroya patagonica, 25ft.; Juniperus recurva, 30ft.; Taxodium distichum pendulum, 35ft. by 3ft. 3in.; Larix europæa pendula, 30ft. across; Fagus betuloides, 40ft. by 4ft. 7in.; Castanopsis chrysophylla, 15ft.; Ilex dipyrena, 26ft.; a Lucombe oak, 82ft. by 10ft.; and a Tulip tree 76ft. by 8ft.

Prideaux Place.

Padstow, on the far north-western side of Cornwall, overlooking the little harbour of the same name, is a small town of ancient date, about a mile from the sea, and set on the side of the broad estuary of the River Camel. In the time of Edward III. Padstow supplied two ships for the siege of Calais, but its usefulness as a port of call is materially reduced by the huge sand bank, the Doombar, that silts up at the mouth of the harbour. There is a local tradition that St. Patrick landed at Padstow, and also one to the effect that the sand bar that almost blocks the harbour is due to the dying curse of a mermaid who was shot in Padstow Bay. I am not prepared to agree with Leland that Padstow is a "good, quick fischar toun, but onclenly kepte," because I saw it at the close of about twenty-four hours' rain.

My objective was Prideaux Place, the ancient seat of the Prideaux family, and now the home of Colonel Prideaux-Brune. This imposing house stands on high ground overlooking the town and occupies a very commanding position. It is in castellated style, and was begun in 1588 on the site of a monastery supposed to have been founded by St. Petroc, and one that was destroyed by the Danes in 981.

The conformation of the gardens at Prideaux Place is extraordinary. There are really eight gardens; that is to say, the gardens form a sort of crescent, or rather a horseshoe, and are divided by roads or rights-of-way into no fewer than eight portions. The pretty church is practically within one of these portions, and it is now, and always has been, well cared for by the Prideaux family. The font of Cataclews stone was once famous because in the days when hanging was one of the commonest forms of punishment, it was believed that anyone baptised in it would be preserved from the gallows. It lost its virtue, however, when one who had been christened in it turned highwayman, and suffered the extreme penalty.

The character of the house, and some idea of its spacious terrace walks and spreading lawns may be gathered from the accompanying illustration, but the picture cannot show the fine dracænas along the terrace front, nor can it clearly indicate the wonderful plants that clothe its walls. Those familiar only with Ficus stipulata (F. repens) as a pot plant, or even covering the wall of a warm house, would be surprised to find it a thick-stemmed creeper here, rising fully 32ft. high and filling a broad space. Enormous Banksian roses adorn the south front, and they are the largest I have ever seen. At the end of the house, near the stables, is a splendid old tree of Benthamia fragifera, and close by is a huge fig tree, while Solanum jasminoides flourishes against the stable walls. At the eastern end is a fine Magnolia grandiflora. Right in front of the house, lower than the terrace, is a small deer park, and the garden runs almost round it, providing some delightful walks among the trees, one of which, showing the free use that is made of Miss Jekyll's strain of polyanthuses, and the great breadths of all kinds of daffodils, is herewith depicted. Hartstongue ferns are so abundant in the woods as to provide another interesting feature.

[Photo: W. Thoroughgood.

SUB-TROPICAL PLANTS AT PENCARROW.

Behind the house there is an interesting little flower garden in front of a very pretty conservatory. The illustration shows that this part of the grounds is terraced, indeed, terraces and sharp slopes and steep climbs are the order all over this estate, so curiously perched on the crest of the hills. Were it not for the fine trees that abound, beech especially, the position would sometimes be an unpleasant one. Cannas are a feature of this flower garden, and though those in the beds are lifted annually to make room for spring bulbs, those in the border are only lifted when new stock is needed, and they have been left out unprotected for ten consecutive years, and remained unharmed. Close to the conservatory wall the Belladonna lilies are a great success. The little fountain basin is the home of Aponogeton distachyon, that is rarely out of bloom, and close by this is a very large plant of Griselinia littoralis.

Another pretty garden is the one devoted to herbaceous plants and roses. Of phloxes there is a fine collection, and these are splendidly grown in large variety. The scarlet-flowered Lobelia Queen Victoria (cardinalis type) is not lifted each autumn, and housed carefully as with us in the London district, but is left out all the winter, and then, about the middle of May, when strong growths begin to push, the plants are lifted, parted, and replanted. It will thus be seen that even in this part of Cornwall the climate is much more kindly to the gardener than it is at, say Kew.

It is a quite easy matter to pass out of any of these more closely and trimly kept parts of the garden into the surrounding woodland walks, but nowhere is gardening neglected. In the springtime the ground beneath the trees is ablaze with daffodils, and, later, aglow with bluebells, while primroses and polyanthuses, from blue to maroon, are in bloom in all but the hottest part of the year. There are many surprises at Prideaux Place, and not the least is the Quarry Garden, that shows how an otherwise unsightly part may be made beautiful. Right through the natural rock that carries a roadway, a big tunnel has been blasted, and through this the bottom of the old quarry is reached. All sorts of climbing and drooping plants drape the stone sides, and the pool below is the home of many kinds of nymphæas. The planting all around is of a most informal character, and in some cases it has been hard work to provide a sufficient depth of soil for the plants. Choisya ternata is splendid here, and so, not far away, is Gunnera manicata. Phormiums grow like weeds, and acanthuses are very much at home. The various forms of the Japanese Rosa rugosa provide another fine feature, and all around these there are big patches of anemones. Anemone appenina is particularly fine, but Mr. Brown, who is deeply in love with the garden he has charge of, says they would be much finer were it not that the pheasants have a great liking for the roots of this species, and annually levy tribute from the Quarry Garden. In this sheltered spot bamboos never look rusty, while Cyrtomium falcatum flourishes quite unprotected, and Eryngium pandanifolium, a noble plant with huge glaucous leaves, is also quite at home, and has flowered here.

But I must conclude with a mere mention of the fine eucalypti, and dracænas, of the laburnum and lilac walk, of the well-kept kitchen garden, of the chrysanthemums, the freesias, and excellent Malmaison carnations, and the quaint old grass walk, where still remain the old guns forming the battery set up by Henry VIII. to defend Padstow Harbour.

Trevarrick.

A little way down the hill from St. Austell Station there is a fine old house set in a well-wooded and charming old-world garden. You look over the fence and at once the thought comes that here there must have lived some who had a great love for their garden, and spared no pains to make it a distinct and unique one. This is Trevarrick, the old home of the Shilson family, and the cradle, so to speak, of the cult of the Himalayan rhododendrons. It is now, and has long been, the residence of Mrs. Hitchins, and her eldest son, Mr. Martin F. Hitchins, both garden lovers, and the latter a keen florist, and as well known as an expert among sweet peas as

[Photo: J. E. Oatey.

A FINE SPECIMEN OF THE COMPACT FORM OF PINUS INSIGNIS AT PENCARROW.

among all that pertains to the production of China clay, for which St. Austell is famous.

The rhododendrons at Trevarrick are very fine, and they include some of the finest arboreums that can be found. There is a magnificent specimen right in front of the house, and another of R. barbatum, 20ft. high, in full view of the dining-room window. At every turn, during a walk through the garden, the wonder of these splendid plants grows. Of course, arboreum varieties are the most in evidence, but there are also splendid specimens of R. niveum, R. cinnamomum, R. argenteum, R. Maddeni, R. Hodgsoni, and the pretty pink R. Thomsoni, as well as a whole host of thriving seedlings.

Glorious must be the many fine specimens of Embothrium coccinea, when ablaze with its scarlet flowers, and charming, too, must be Benthamia fragifera, when adorned with its multitude of white blossoms. Other arboreal treasures are a giant Pinus insignis, a Sciadopitys verticillata, 25ft. high; a very fine pair of Cupressus macrocarpa; a magnificent tulip tree, much larger than the fine specimen in the gardens of University College, Reading; a grand old English oak, and a splendid hickory, with great spreading branches, that is probably one of the biggest in the country.

Daffodils, pansies, and carnations abound, and there are fine collections of these, but they are under the special care of Mr. Herbert Hitchins, while the sweet peas are Mr. Martin Hitchins' special hobby, and right grandly are they grown. Mr. Hitchins believes in thin planting, in single rows, and the rows very wide apart, and the results justify his belief. He grows a goodly number of varieties each year, and his knowledge of these popular flowers led to his election upon the Floral Committee of the National Sweet Pea Society.

It is interesting to observe the love of flowers that runs through the family. Every one of Mrs. Hitchins' sons is a keen amateur gardener, and one can imagine their love of flowers and plants is due as much to the influences of the Trevarrick garden as to any inborn love they started with. Two other brothers resident in St. Austell make roses and orchids respectively their hobby.

CHAS. H. CURTIS.

PRIDEAUX PLACE, PADSTOW.

WICHURAIANA ROSES.

The title of Wichuraiana is now applied to a large number of varieties, as well as to the type introduced from Japan about 1887, and distributed here by Dawson in 1893. This latter has single, small pure white flowers in large clusters, with prominent yellow stamens. It flowers very freely throughout summer and autumn. From this we have obtained many beautiful hybrids, so that the original kind is generally alluded to in the rose trade as "Wichuraiana, The Type."

It was in 1900 that Messrs. Barbier Brothers, of Orleans, sent out their first hybrids, and now many of our best weeping and rambling roses belong to this class. Mr. W. A. Manda, and Messrs. Conard and Jones sent out three really good varieties the year previous; Evergreen Gem, a cross between the type and Madame Hoste, is a pale buff-white, a little more than semi-double, of extraordinary strong growth, that has sweet briar fragrance; Jersey Beauty, a cross with Perle des Jardins, is single, large, and showy, and being so very hardy is a capital substitute for the tender Sinica and Macartney roses.

In 1900 we had Alberic Barbier, a fairly deep yellow when in bud, and opening to a creamy-white. This is one of the earliest to bloom here. René André is a cross with L'Ideal, and gives us much the same comminglings of colour, and, what is of equal value, we have the delicious perfume of this beautiful, but somewhat tender Noisette. Gardenia, in the bud, is deep yellow, and three of the buds, backed by their own shiny foliage, make an ideal coat bouquet. It grows paler with age, but is one of the best, and was probably named because of its perfume, which closely resembles that of the stove shrub. Eliza Robichon, a very pretty semi-double rose, shaded with pale yellow, is one of the best in this class, being exceedingly free flowering, and a little neater in habit than most.

The varieties named above are remarkable for their creeping habit, and are never seen to greater advantage than when upon tall standards, as weepers, or planted high up on ruins and allowed to droop down. I have only mentioned a few of the best known, but these are being added to annually. They are extremely hardy, profuse of blossom (some of them almost perpetual), and decidedly the most evergreen of any rose—all points in their favour; nor have they been attacked by mildew and red rust with us.

A cross between R. Wichuraiana and the multiflora or polyantha section has given us the beautiful group of which Dorothy Perkins, Hiawatha, etc., may be taken as examples. Here we seem to retain the vigour and hardiness of both parents. Lady Gay appears a little stronger with us than Dorothy Perkins, while Minnehaha and The Farquhar Rose are stronger still. I am only writing of them as they grow in quantity side by side here. They are certainly distinct, both in growth, colour, and form of truss. The Farquhar rose is a cross between R. Wichuraiana and Crimson Rambler, and conforms to one's idea of what that might produce. Strange to say, Minnehaha, very much like it, is a reputed cross with Paul Neyron; a parent so out of character with its offspring that one almost doubts if Mr. Walsh (the raiser) can be correct in its pedigree.

I have several of the newer varieties, and look forward to very pleasing results if the pedigree is given correctly. For example, Wichuraiana x Souvenir de C. Guillot; this is from three distinct raisers. Also crosses with Eugène Resal, Madame Charles, and Laurette Messimy, but more of these next year, after a fuller trial.

I much prefer these roses upon their own roots, and they are so full of vitality that the aid of a foster stock is not needed. This ensures that all shoots from the base are rose, and not stock suckers, and it is just from here that the most serviceable growths spring. I would like to give a warning word in planting these. They commence growing very early, and must be afforded a little extra care, especially when treading the soil about them firm.

Uckfield. A. PIPER.

BERBERIS AQUIFOLIUM.

It is impossible to overestimate the value of this evergreen species for garden decoration, or for undergrowth in woods and plantations, for it thrives in both good and poor ground, and succeeds on dry banks and beneath the shade of trees, where few things will grow. Either planted alone, or intermixed with Rhododendron ponticum or aucubas, it is equally desirable, and can be kept to almost any height between one and four feet by pruning. The foliage, of course, is ornamental during the whole of the year, but it is doubly so in winter, for at that period the leaves take on a bronze or purplish, or sometimes red hue, which makes them of value both for the garden and for cutting, to use in companionship with flowers for house decoration. The flowers also have something to recommend them, for they open in early spring, are yellow in colour, and are borne in good-sized terminal inflorescences.

The type is the most valuable plant for general use, but there are several well-marked varieties which are worth inclusion for special positions. Of these the following are specially noteworthy: B. a. fascicularis and B. a. Murrayana are two strong-growing varieties, which grow much taller than the type, and are of somewhat looser habit. B. a. latifolia and B. a. macrophylla are remarkable for their large leaves, B. a. rotundifolia for its large rounded leaflets, and B. a. undulata nana for its dwarf habit.

Kew.

BRITISH FERN CULTURE.

It seems a very bold thing to assert that amid all the various branches of horticulture to which we owe the brilliancy and beauty of our present shows, that of our native ferns, in their varietal character, is far and away the most interesting to anyone who takes the trouble to investigate the subject. There is, for instance, not one among the rest which can claim to be purely and entirely British, and the outcome of natural sports found exclusively within the British Isles. We may take any one that may be cited in contradiction, and we shall invariably find either that the plant concerned is an exotic to begin with, or that the varieties exhibited are partly imported, having been originated by foreign cultivators. Furthermore, we shall discover that the bulk of the varieties are due to long-continued selection of small points, or to hybridisation, coupled with subsequent selection, and rare indeed will be the case where the exhibitor can assert either that he found the plant growing wild or that the specimen shown is the more or less immediate outcome of such a discovery.

POLYANTHUSES ALONG THE WOODLAND WALK AT PRIDEAUX PLACE.

Again, when we confine our argument to ferns we find that, varied as the exotic ferns are, their diversity is mainly specific, and not varietal, and that despite the great number of species now existing in our collections, the proportion of improved varietal forms to which they have given rise is incomparably less than in the case of our native ferns, which, roughly speaking, have yielded 2,000 wild varieties from only a score of species, the remaining score being ignored as having produced but few. The British fern hobby, or cult, is also the only one which is associated with a sympathetic coterie of hunters as well as raisers. Unhappily, the old coterie of pioneers, Wollaston, Ure Jones, Dr. Fox, Lowe, Fraser, Moly, Padler, Carbonell, and others, have mainly passed away, but a few remain to leaven a succession now that renewed interest is being shown in these peculiarly wonderful natural productions. Nobody who has not experienced it can imagine the delight engendered by the discovery of a thoroughbred and beautiful new variety, full grown, and in its prime, in a hedge, a dyke, a bit of woodland, or in a picturesque glen, or even on the open moor, anywhere, in short, where ferns are at home. There it stands amid its common fellows, and undoubted progenitors, from which it may differ in a hundred varied ways, tasselled or frilled, or fringed or condensed, crimped or curled, and yet, search as we may, we shall find no approach to such characters in any of the plants around. Its origin is a mystery. Nature, in some occult way, has inspired a spore or a bud, and instead of the old form arising a new one has appeared for the hunter's delectation. Carefully removed and cultivated it retains its character indefinitely, and its spores, moreover, will reproduce it, generally truly, but often on varied lines which permit of improvement by selection, while now and again its offspring will make a bound, as it were, and give altogether unexpectedly transcendent results.

We are not exaggerating here; this has occurred several times in our own experience, and been ratified by R.H.S. first class certificates of merit. On the other hand, the hunter often comes across small plants, either as seedlings or growing on old walls, under stunted conditions which preclude full development. In these his sharp eye detects something unusual, and he takes them home for trial. Sometimes, under congenial conditions of growth, their normality asserts itself, but not infrequently very good varieties are found in this way, and again we say that no outsider can gauge the pleasure experienced by the finder when he notes the greater and greater development of possibly new and unforeseen characters as the youngster or dwarfed specimen assumes the adult form.

Such research, too, carries us into the most beautiful parts of the country, since it is always in the verdant lanes of our western counties, the fern-clad banks, old walls, and stone dykes of the high roads there, in the heart of the woodlands, by the umbrageous banks of the mountain stream, or on the very flanks of the hills themselves, that the hunter finds his gems, inspired always by the knowledge that wherever there is a fern there is a chance of a find. This fact is peculiarly difficult to bring home to outsiders. Over and over again we have been informed by friends, after a country outing, that there were "plenty of ferns, but only common ones," they being apparently unable to grip the idea that it is precisely among these "common" or normal ones that the varieties originate, and that no place exists where the varieties would constitute the ferns of the locality by themselves.

The fern hunter in search of new localities is often misled by reports of abundance, only to find, perhaps, after a long journey, a bracken-covered country, with no other ferns to speak of. Even the bracken (Pteris aquilina) is, however, a by no means uninteresting fern, from the varietal point of view, since it varies con-

CONSERVATORY AND FLOWER GARDEN AT PRIDEAUX PLACE.

siderably, and congested, tasselled, curiously twisted, and revolved or tubular forms have been found, in this case in quantity, some acres of a prettily tasselled variety existing at Faygate, Sussex.

British fern culture, apart from its unique character in the respects indicated, possesses also the advantage that as all the plants are native, they are quite hardy, so that no expensive heating apparatus is required either for their maintenance or propagation. The sowing of spores of thoroughbred varieties is of absorbing interest, by virtue of the fact that new and improved forms are very apt to result, as already indicated, and, as a matter of fact, no one who has once caught the fern "fever" by a fortunate "find," or a successful raising, ever loses the taste for the cult, but becomes a lifelong student, and, as a rule, the happy possessor of a collection of individual as well as general interest. The writer has such a collection of several hundred varieties of the élite, a good percentage of which are his own personal finds, or those of his intimate friends inspired by his example, plus a number of unique gems obtained by selection. Can as much be said for any other branch of purely indigenous and amateur horticulture? We doubt it extremely.

Chas. T. Druery, V.M.H., F.L.S.

DESIRABLE INCURVED CHRYSANTHEMUMS.

Although the varieties to which I wish to call the attention of cultivators are not all new, they are not what might be termed common. As this type is so little appreciated at the present time, and as desirable new varieties are very scarce, cultivators who have not had much experience are glad to know the names of desirable sorts. Clara Wells is the best new variety for some years. It was raised by Mr. Pockett in Australia, and is so easy of cultivation that the bloom develops well from any reasonable bud. In form it much resembles C. H. Curtis, but is broader across the top and therefore more globe-shaped. The florets are of medium width and thoroughly incurving. In colour it is a rich cream flushed at times with rose.

Daisy Southam, rich yellow, with a bronze suffusion, shapely and good in every way.

Mrs. J. Wynn is best described as a white Curtis; at times it has a slight flush of lilac.

Godfrey's Eclipse was shown remarkably well last season. The soft yellow blooms, with their neatly incurving florets have found many admirers.

Margaret Brown reminds one much of Princess Teck in its form; the colour is purple lilac.

Boccacio is a neat flower of a rich yellow hue, quite an acquisition.

E. Molyneux.

Tomatoes.—Early-sown seed will have produced plants that require to be pricked off and potted according to the system of cultivation they are intended for. If they are to be fruited in 7in. pots, put each plant in a thumb pot, but if it is the intention to fruit two plants in a 10in. or 12in. pot place two plants, one at each side, in a 60-sized pot. Use a potting material consisting of loam lightened with some spent mushroom-bed manure and sand. Place the plants in the lightest position near the roof glass, in a temperature of about 60 deg. Apply water very carefully until the young roots have become active.—C. Flack.

FEBRUARY.

"His island voice then shall you hear,
Nor ever after separate
From such a twilight of the year,
Advancing to the vernal gate."
Meredith—"The Thrush in February."

It is a truism that the temporary deprivation of our blessings enhances our appreciation of them, and it is perhaps partly owing to that fact that we enjoy the first bright spring days of February after being more or less shut off from our gardens during December and January, either through the weather or from want of daylight. It has been said that to thoroughly appreciate the country one must go and live in a big town, and certain it is that one takes a renewed interest in the garden at this season, after, as it were, the vacation. The old saying about "February fill-dyke, black or white," has only been true exceptionally of late years. It is a month when we often get some magnificent weather, as well as some of the reverse, and it reminds one of the rhyme about the little girl:

"And when she was good she was very good indeed,
And when she was naughty she was horrid."

It is the month when the thrush sings its best in the morning twilight, or when, rather, we hear it at its best owing to the fewness of other songsters at that season.

"Summer is coming, summer is coming,
I know it, I know it, I know it.
Light again, leaf again, life again, love again."

. . . . .

"Love again, song again, rest again, young again,
Never a prophet so crazy!
And hardly a daisy as yet, little friend,
See, there is hardly a daisy."

So sang Tennyson, and we have all enjoyed it at this season, though we have not such powers to express our delight as the poet had. The blackbird, too, is often then at his best, and though both he and the thrush afterwards become, through County Council protection, such a pest in many districts during the summer, yet it must be admitted they do give us something in return. Many of us will agree with the late W. E. Henley's sentiment:

"The nightingale has a lyre of gold,
The lark has a clarion call,
And the blackbird plays but a boxwood flute,
But I love him best of all."

But not less than our delight at the young enthusiasm of bird life at this season—our natives before the arrival of the foreigners—is the delight of the garden enthusiast at the sight of things pushing through the soil, and the fruit buds swelling on the trees. We can now say with certainty what blossom there is going to be on all but some of the less definite apples, and it is a time when hope reigns supreme and we are apt, if not to forget, at least not to dwell upon, the bad times which are doubtless in store. Our earliest flowers are beyond the coming out stage, and we have the Lenten roses in full beauty at the end of the month, as well as snowdrops and crocuses, which draw out the first bees of the season and make us fancy it is really spring, as it is, indeed, for the time being.

"And winter sped,
Whirled before the crocus, the year's new gold."

There is more sentiment gathered round the snowdrop than most flowers, and it inspires very different thoughts in people of different temperaments. Wordsworth addresses it as "pensive monitor of fleeting years," and says:

. . . "Once more I see thee bend
Thy forehead as if fearful to offend,
Like an unbidden guest."

While Tennyson hails it:

"Coming in the cold time,
Prophet of the gay time,
Prophet of the May time,
Prophet of the roses.
Many, many welcomes,
February, fair maid."

That is the spirit in which we should contemplate it, but there is so much of interest at this season that it is not really a time favourable to contemplation in the garden, like November or July in their different ways. Though we have the earliest bulbs in flower, many others are daily coming up, and remind us of Coventry Patmore's lines:

"The buried bulb doth know
The signals of the year,
And hails far summer with his lifted spear."

But while enjoying the early bulbs, the heralds of the progress of spring, and the promise of fruit on our trees, it is a busy time when the weather is favourable. We need to have all our plans made, to know what we are going to do with every yard of ground, so that we may be able to "seize the day" when it arrives, for if it is not seized we may have to wait weeks for another. It is the month for sowing seeds under glass, and even out of doors at the end of the month in a favourable season, remembering that many of our hardy annuals never do so well as when sown at the end of February, notably the Shirley poppies, while the sweet peas should be well up in pots, so that we may get that early start which is so essential to enable them to hold their own in dry weather.

It is in February that we want to get forward, so that when the rush comes in March we may not have to use precious time in doing anything which might have been done before, such as the making of preparations for protecting wall fruit blossom, removing the mulch from newly-planted trees to let the sun warm the soil, winter washing the fruit trees, loosening the surface soil amongst the bulbs, and so on. The great secret of being able to cope with the work in busy seasons is to have everything fully ready for grappling with it, even down to the writing of the labels for seeds—trifling details, but the foresight which has attended to them is one of the principal causes of men being ahead of their neighbours year after year.

Alger Petts.

Magnolia stellata.—It is always interesting to notice such plants as seem specially designed to flourish in small and large gardens alike. Magnolia stellata is now represented in some gardens by old specimens which, in large gardens, often take the form of groups full of historic interest. In the open garden it is one of those delightful harbingers which practically usher in the spring, and, when carefully planted and well grown, its beauty and interest increase with the years. Planted in a warm, sunny spot, and well sheltered from winds, which cause the branches to chafe and bruise the flowers, and given a cool loam or peaty soil free from lime, it soon grows into a large bush, and unfolds a wonderful picture in its snowy purity. The flowers come in advance of the leaves, and it is often advisable to protect the shrub by a light covering of tiffany, in the event of frost coming to spoil the flowers. Magnolia stellata is one of the best subjects for flowering in pots for the decoration of the conservatory in spring. Under these conditions one can enjoy the chaste beauty of the flowers to the best advantage.—Thomas Smith, Walmsgate Gardens.

ECKFORD'S PEAS.

Some sharp-eyed reader will probably imagine the writer or the printer is guilty of omission in the title to these few notes, so I hasten to point out that the title is a perfectly good and correct one. So correct, in fact, that if the firm of Henry Eckford, Wem, Salop, had not achieved the world-wide popularity it now enjoys for sweet peas, it would be quite famous for culinary peas. I have drawn attention on several occasions in these pages to the great work the Eckfords have accomplished in the improvement of culinary peas, and it is rather aggravating to find now and again someone acknowledging utter ignorance of their very important work in connection with this useful and much appreciated class of vegetables.

SWEET PEAS FOR THE GARDEN, IN MR. J. S. ECKFORD'S HOME GARDEN AT TILLEY, WEM.

One can hardly talk of sweet peas for two minutes without reference being made to the Eckfords, father and son, and as long as sweet peas are garden favourites—and that will be just as long as flowers are grown—the splendid pioneer work of Henry Eckford will not be forgotten. But in these days of keen business, and while sweet peas are immensely popular, the memory of a clever man, even though he created the industry, will not keep a business going. There must be continuous progress in the matter of new varieties, a clever anticipation of the public demand, and standard varieties must be kept true. But Mr. John S. Eckford was his father's right hand man for so many years that he fully understands the signs of the times. One has but to visit Wem year by year, as I have done for many years past, to see how wonderfully the business progresses. Last summer the office accommodation and the packing and despatching departments were considerably enlarged, and yet only two years before the premises were enlarged and brought quite up to date for the purpose of coping with the increasing demand for Eckford's seeds.

Sweet Peas.

Not many years ago the home farm at Wem sufficed to provide the bulk of the sweet pea seed needed; then a large piece of ground was taken a few miles away, and large blocks of standard varieties of sweet and culinary peas were grown under special arrangements in Essex. But all these would not provide sufficient stock, and so a farm was taken in Essex for seed production, where last summer about sixty acres of sweet peas were grown, and the rows, if put end to end, would have measured nearly 200 miles. There must be some good foundation for such an increase of business as this indicates, and this foundation is purity and fixity of stocks, the very careful output of new varieties, and judicious advertisement. Wherever they have been tested, the Eckfordian sweet peas—I mean those obtained from Wem—have always been remarkably true to name. Even the beautiful Countess Spencer sweet pea, so fickle when first distributed, has always been a true stock at Wem. It is my firm belief that the Eckfords' success is just now due more to "fixity" than even to novelties, because so many people have been sadly disappointed with the results obtained from high-priced novelties sent out long before they were fixed.

Eckfords led the way in regard to novelties, and they are now in the forefront in the matter of fixity. It must not be thought that Mr. John Eckford despises novelties. By no means. I saw many fine things at Wem last summer among the waved section of sweet peas, but the reply to a very obvious question put was, "No; we are not quite satisfied with the fixity of the stock," or "That is quite fixed, but our stock is not yet large enough for distribution, and we do not care to offer a variety and then have to disappoint half our customers." This season, in addition to a few of the finest novelties from other sources, Mr. Eckford is sending out three varieties unobtainable elsewhere. These are Dodwell F. Browne, a fine waved variety that, to my way of thinking, has more scarlet in it than has The King, a variety with which it may be compared. Mrs. Charles Masters, a charming bicolor, with rosy-salmon standard and creamy wings, a variety that will find great favour for garden and home decoration; and Annie B. Gilroy, a beautiful, bold, cerise self, that is especially effective under artificial light. These are the three special novelties for 1909, and there has already been a keen demand for them, as also has there for James Grieve, one of the yellowest of sweet peas; this is not waved, but it gives a deeper note of colour than any other variety in its class, and won a high position in the National Sweet Pea Society's trials at Reading in 1908. This is not the place to give a selection of sweet peas, but it may be noted that Eckford's catalogue is so well arranged that it should be in the hands of every sweet pea lover.

It is at Wem that one has an opportunity of seeing new sweet peas in the making, and a walk among the long rows of seedlings, all from carefully cross-fertilised seed, in company with Mr. John Eckford, is one of the most pleasant and instructive that could be desired. The ideal yellow, blue, and maroon sweet peas are yet to seek. In the case of the latter colour the great difficulty is that of eliminating the purple from the wings and keel, but this difficulty is being overcome by Mr. Eckford, who, fortunately, has no intention of distributing the intermediate varieties obtained in the process of evolution. Mr. Eckford has set his face against excessive frilling or waving, and will have none of those flowers that are without form, and that look more like a few limp, crumpled petals than a dainty and beautiful sweet pea. Over-Spencerised flowers are my pet aversion, and I was especially glad to find such a high authority as Mr. J. Eckford in agreement with myself on this point.

Other Flowers.

Sweet peas are the great feature at Wem and in Essex, and many a visitor has eyes for nothing else. But when one has time to look round it soon becomes evident the same care that has brought the sweet pea to such a high position is being expended upon other popular flowers. We are in danger of forgetting that Mr. Henry Eckford had obtained fame as a verbena raiser before he took up sweet peas seriously, but at Wem one finds splendid seedlings, showing that the strain has been perpetuated and the colours increased. It is worth noticing that verbenas are becoming popular again, treated as annuals, for summer gardening. Marigolds and pansies attract attention, and the latter are especially good, particularly the strain in which the bronze colouring has been so well developed. The keen dahlia grower naturally depends upon named varieties for his display, but those who are not so keen, and who have no wish to compete at a dahlia exhibition are coming to find that dahlias can be quite easily raised from seed, and that if a carefully selected strain is obtained excellent displays of bloom result. A few firms make a speciality of these garden dahlias, from seed, and among them Eckfords take a leading position, because they have been selecting and re-selecting their seed stocks for many years. Begonias, primulas, stocks, antirrhinums, and tropaeolums are a few other flowers specialised at Wem. One can hardly say anyone specialises in the ornamental grasses that are so suitable for association with cut flowers, but the Eckfords have always kept these pretty and graceful plants before their customers, and grown them largely at Wem, consequently they know the best kinds to grow for certain purposes.

Before passing from the flowers it is worthy of note that Mr. J. Eckford's own garden at Tilley, Wem, is a perfect picture in summer time by reason of the profusion of blossoms that encircle it and surround the little lawn. The air is redolent with the perfume of sweet peas, mignonette, and stocks, and the sweet peas are grown on wire netting strained round four upright posts, kept in position by means of cross-pieces nailed over the top after the stakes have been driven well into the soil. The plan has proved so successful, as I know from personal observation, that Mr. J. Eckford is now offering suitable prepared stakes for the convenience of those who desire to grow sweet peas in this manner for garden decoration

SWEET PEAS FOR SEED AT ECKFORD'S SEED FARM IN ESSEX.

Culinary Peas.

The Eckfordian culinary peas are notable for their robust habit, purity of strain, and free-cropping capacity. I shall not soon forget the rows of The Prior I saw in a Malpas garden several years ago, where it was being tested privately before being sent out. It is a grand variety, either for home or exhibition, and it fills out its long pods with large, finely-flavoured peas, while in the matter of crop I have not seen a variety to beat it. I am particularly fond of Critic and Censor, two good midseason peas, the former having peas that retain their beautiful green colour all through the cooking process, and come to table in a very attractive and appetising manner. Censor has very large peas, and these are of exquisite flavour. Centenary, a fine maincrop pea; Record, a grand second early variety; The Bruce, finely flavoured; and Shropshire Hero, a very productive second early pea, are a few that can be confidently recommended among those raised at Wem. There are many others suitable for various seasons and purposes, and all are heavy croppers. It will thus be seen that the Eckfords have not confined their attention to the decorative side of gardening, but have entered heartily and successfully into the work of improving vegetables—a work that is being prosecuted with greater vigour than ever now that a larger acreage has been secured for experiments and for raising good sound English seeds.

C. H. C.

NEW CONTINENTAL CHRYSANTHEMUMS.

It would appear that M. Calvat is well ahead of any of his countrymen in the raising of new chrysanthemums, but he has found a serious rival in Pockett, and probably one or two of our home growers. At Tours and at Paris he was eminently successful last year. At the former place an "objet d'art" was given to him, while at Paris a "grand prix d'honneur" was awarded him for his collection.

Some of his novelties were quite up to the old standard, and but for the immense competition with which he has now to deal they would be certain to occupy a high place on our showboards, as many others of his have done. I took notes of them all for the purposes of future identification, and the best from an English point of view I specially marked. The information may be useful to some of our growers, and hence I am tempted to give a short list of these most promising novelties.

Ferdinand de Bièvre. — A monster Japanese, with rather broad florets, a very closely built, solid, and compact flower of great size and substance; colour, pale yellow shaded chestnut-red.

Rachel L'Abbé.—A huge Japanese, having rather narrow, twisted, and intermingling florets, curly at the tips; a massive deeply-built flower; colour white, slightly tinted green in the centre.

Mme. E. Bonnefond.—Another massive bloom, very full and double; a gracefully reflexing flower, with florets of medium width; colour, rich golden-apricot, passing to golden-yellow in the centre.

General Sauret.—Also a huge Japanese with a very full centre; medium-sized grooved florets; pure golden-yellow, curly at the tips; extra fine.

Souvenir de Mme. Gagnairè.—A large Japanese of fine form. It has very long drooping florets of medium width, and makes a bold imposing flower; colour bright pinkish rose, with silvery reverse.

Belle Esterelle.—A grand novelty in the Japanese section with long, spreading florets, which are of medium width; colour pure golden-yellow.

Calvat, 1908.—At Paris the name was altered to Blanche Delcloque; Japanese, very broad florets; tips slightly incurved; a very full flower of a fine shade of bright rosy amaranth, with silvery reverse.

Paul Delaroche.—Also a huge, massive Japanese of great solidity; the florets are of medium width, twisted and intermingling, forming a spreading flower; clear pearly blush shaded lilac-mauve.

Reine Fiammette.—A finely built Japanese, very full and double. The florets are of medium width and reflexed; bright rosy amaranth or purple.

Miarka is a solid, compact incurved of a high order of merit; the florets are grooved and of medium width. Colour pure white, slightly tinted.

Mme. Travouillon.—Japanese; very close and compact in form; a long petalled flower of great size; a pretty shade of rosy lilac-mauve.

Belle Tronchoisè.—A very long petalled Japanese, and a big flower; the colour is rich reddish salmon-rose, with golden reverse.

Rev. W. G. Sharpin.—Japanese; one of the biggest; the florets are grooved and very broad; colour on the inside dull old rose, with golden reverse.

There were many others shown, but the above named in the form exhibited are those most likely to please English growers, and most of them were certificated by the Paris Floral Committee. Others that received this distinction, but which I have not specially marked in my notes, were Melisandre, Mme. Max Chabuel, Mme. Jules Maggi, Chrysanthemiste Durand, Peintre Bienvetu, Cecilia Monteil, Achille Fenin and Mme. Julien Ray.

C. Harman Payne.

Sir Michael Foster's Snowdrop (Galanthus Fosteri). — A pretty snowdrop, when seen in its best forms, is that called by the revered name of the late Sir Michael Foster, and known to the botanist as Galanthus Fosteri. The species is a handsome one when seen in the best varieties, but this is expressly mentioned, as, like many other snowdrops, it is extremely variable in its size and other qualities. The first bulb I secured was a very disappointing form, and some cut flowers the late Professor Sir M. Foster sent me soon after made me despise the plant I had bought. Since then, however, I have secured a better variety, but with me it has never come up to the high standard of Sir Michael's flowers, which were produced by the bulbs originally sent him from Amasia, or by their direct progeny. The handsome leaves, and equally handsome and most charming flowers, make this snowdrop, when a good type, of the highest beauty. It is as good a grower as any of the other snowdrops from the South, and I find it hardy well North of the Tweed. It should be borne in mind in autumn, and some bulbs secured, planting them from three to even six inches deep.—S. Arnott.

VARIETIES OF SCAB IN POTATOES.

Owing to the destructive effects of the fungus causing the wart disease of potatoes, it has become a matter of much importance that growers should become sufficiently acquainted with the several forms of scab by which the potato crop is infected, as to be at once able to distinguish them. Hence the fully-illustrated article on the varieties of potato scab which appears in the current issue of the "Journal of the Board of Agriculture" is of much value, and we reproduce the following:

Scab Due to Mechanical Injury.

This type of scab is recognised by the very superficial nature of the scars, which often cover the greater portion of the surface of the tuber, and are entirely due to mechanical irritation of the skin of the potato during the early stage of growth. The most general cause of irritation is the presence of ashes in the soil, consequently it is very prevalent in the neighbourhood of towns, where night soil is used as a manure. In an experiment conducted at Kew, for the purpose of proving the correctness of the above statement, twelve potatoes free from scab of any kind were planted in soil mixed with ashes. A second row, parallel with the first, planted in soil containing no ashes, acted as a control. When the crop was lifted, all the potatoes grown in the land containing ashes were badly scabbed, whereas those grown in the land not containing ashes were free from scab. This experiment has been repeated on several occasions with similar results.

In addition to ashes, certain climatic conditions favour the formation of the scab under consideration. During a dry period the surface of the quickly-growing tubers presses against the comparatively unyielding soil, with the result that the skin is injured. As such injured tubers continue to increase in size, the original minute scars are stretched wider and wider, and become bounded by a somewhat raised border of wound-cork, the result being scab. This type of scab is often very prevalent on potatoes grown in sharp sandy soil during a dry season.

Unless complications follow, the injury caused is slight, as the wounds are only "skin deep," and such scabbed potatoes may be used for "sets." In many instances, however, mechanical injuries to the skin enable eelworms, bacteria, fungi, etc., to gain an entrance into the tuber, which may result in its complete destruction.

Wart Disease or Black Scab of Potatoes.

This disease is recognised by the presence of one or more irregularly shaped, corrugated masses, or warts, projecting from the surface of the tuber. These warts are pale when young, but gradually assume a blackish colour with age, due to the presence of myriads of dark-coloured spores belonging to the fungus causing the disease.

The young "sprouts" only are attacked by the fungus, the substance of the tuber at first remaining free from injury. When a sprout is attacked, the irritation set up by the fungus causes an excess of food material to enter the infected area, which rapidly increases in size and spreads over the surface of the tuber. In cases where several sprouts are attacked, the entire surface of the tuber often becomes covered with an irregular, cauliflower-like mass.

In some instances, when the haulm is lying on the ground, the young leaves are attacked and distorted by the fungus; very young tissue, in fact, of any portion of a potato plant appears to be liable to infection.

When the fungus spores are mature the warts commence to break up and decompose, thus liberating the spores, which pass into the soil. At this stage various kinds of fungi and bacteria gain an entrance into the tuber and complete its destruction.

After years of failure, the spores of the fungus causing black scab have at last been induced to germinate. This advance enables the systematic position of the fungus to be determined with certainty, and will also aid in formulating preventive measures now that its life-history is known.

Scab Caused by Millipedes.

Among the various kinds of millipedes, popularly known as "false wireworms," Julus pulchellus, L., is the greatest enemy to growing potatoes. It varies from half to three-quarters of an inch in length, and is not much thicker than an ordinary pin, pinkish-white in colour, with two rows of small purple spots running its entire length. Although not generally a primary cause of injury, julus readily takes advantage of any minute wound, which it quickly enlarges by feeding on the sound portion of the tuber. In some instances numerous shallow cavities are formed in the flesh of the potato, and as each wound becomes surrounded by a raised border of wound-cork, a scabbed appearance results. In other instances small holes roughly circular and of varying depth are produced, whereas in some cases, as when following on an attack of Spongospora scabies, Mass., very large cavities are formed, or the tuber may be completely hollowed out. In such cavities hundreds of millipedes are often present. Millipedes are often introduced to the land in leaf-mould or decaying vegetable matter. Lime is the best corrective.

Oospora Scab of Potatoes.

The scab produced by the fungus called Oospora scabies, Thaxter, superficially resembles that due to mechanical injury, but is distinguished by the presence of the parasite, which appears on the wounded portions as a delicate greyish bloom. The entire surface of the tuber is frequently broken up, or scabbed; in other examples the injured portions are more or less circular in outline, and scattered over the surface of the tuber.

Beet, swedes, turnips, and carrots are susceptible to this disease, and should not follow a crop of diseased potatoes, as the fungus remains alive in the soil for some years.

Nitrate of potash, at the rate of two cwt. per acre, has proved beneficial.

Spongospora Scab of Potatoes.

This form of scab, due to the Myxogaster called Spongospora scabies, Mass., was described in detail in the "Journal," November, 1908, p. 592. The certain proof that spongospora is the cause of injury is the presence of the very characteristic spores, which form a snuff-coloured mass on the surface of the wound.

Judging from the very large amount of material received at Kew for examination, spongospora scab is much more prevalent in Scotland than in England.

Pæonia tenuifolia.—One of the plants which is not nearly so plentiful in gardens as it was some years ago is the pretty Pæonia tenuifolia, a most elegant plant in every way, and with a refinement which is not generally associated with the name of the gorgeous, though very beautiful pæonia of gardens. This fine-leaved pæonia is prized as much for its foliage as for its flowers, pleasing though these are. The leaves are divided into a great number of narrow leaflets, all divided again, and giving a specimen a remarkably light and elegant appearance. The deep red flowers nestle prettily among the upper leaves, and both in the single and double forms are much admired. The single variety is less cultivated than the double one, but it appeals more to many than the latter, which, however, retains its flowers rather longer. Pæonia tenuifolia likes a good rich soil, and is a capital plant for the border or a shrubbery border. Its height is from a foot to about a foot and a-half, and its flowering time is in the beginning of summer. Increase is effected by division, but large plants are more ornamental than the smaller.—S. ARNOTT.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

WINTER-FLOWERING CYPRIPEDIUMS.—The bulk of the late autumn and winter-flowering section of cypripediums will now be passing out of flower, and any potting should be attended to. I have never been an advocate of disturbing plants of this section more frequently than is absolutely necessary, therefore, when repotting, liberal pot room should be afforded, such as will not necessitate the repotting of large specimens for at least a couple of seasons. Small plants that require more space, with increased growth, are more suitably treated by annual repotting. Plants with very few roots are best placed in small pots, and, if satisfactory progress is made, more root room may be allowed late in the season by giving the plants a larger pot without disturbing the potting compost into which they have rooted. See that the drainage is clean and ample. These plants require liberal root moisture practically all the year, and therefore every precaution is necessary to prevent stagnation.

THE POTTING COMPOST we find suitable for such species as C. Fairieanum, C. Charlesworthi, C. Spicerianum, and the many varieties of C. insigne, as well as for the hybrids, such as C. Leeanum, C. Actæus, C. nitens, and the numberless allied kinds, is a mixture of about equal parts of turfy loam and fibrous peat, with a small portion of chopped sphagnum moss and sufficient finely-broken crocks and sand added to render the compost porous. The grade of the compost should be varied, but it is advisable not to break it up too finely when specimens of any size are repotted, the reason being that it is desirable to have the compost of a lasting nature for plants that are to remain for a lengthened period in the same pots.

DIVISIONS AND NEW STOCK. — No orchids lend themselves to division more readily than the cypripediums. It is always advisable to examine over large specimens a few weeks before they are potted, and to sever the rhizomes between the growths. It will often happen that large plants of such species as C. insigne will have a number of back growths, and these, unless the rhizome is divided, would probably never produce further growths; but by simply dividing them it is surprising how quickly the dormant eyes of these burst into active growth. Even where plants do not require repotting, it is desirable to look to them annually and make discreet divisions, as every new growth obtained is an advantage to the specimen. If there is a desire to increase the stock, these divisions may be removed at the time of potting, and if placed in well-drained shallow pots, they usually give satisfactory results. Rarer specimens should always be allowed a break and growth, and, if possible, should be divided when root action commences. Take away the leading part without disturbing the back growths if possible.—H. J. CHAPMAN, Oakwood Gardens.

STOVE PLANTS.

SEED SOWING.—Some necessary flower seeds should now be sown, such as Aphelandra Roezli, or A. nitens, asparagus in variety, Acacia lophantha, Clerodendron fallax, gloxinias, gesneras, Grevillea robusta, streptocarpuses, smilax, panicum, cyperus, vincas, coleus in variety, and many others, to provide plants in daily use for decoration. Use clean pots and crocks, and give abundance of drainage. Sow fine seeds thinly upon a damp, firm, and even surface, and cover with a sheet of glass. To destroy insects and warm the soil before using place several old fire bars in the furnace, and when well heated insert these in the soil. When the seedlings appear give air and light to strengthen the plants. It has often struck me that between success and failure in the sowing of seeds and the cultivation of plants the step is but a short one, but that with close observation and well considered plans, reflections upon failures would be but few.

AMARYLLIS.—A portion of the earlier stock cf these bulbs may now be started, and the others brought on at intervals of three weeks, so as to have a succession of flowers over a long period. Before potting the bulbs should be cleared of all decayed matter, and, if insects are suspected, be washed with some approved insecticide. The pots to be used will depend upon the size of the bulbs, but generally a six-inch or seven-inch pot will be found large enough for an ordinary bulb. A suitable compost is two parts rich fibrous loam, one of leaf-soil, and sufficient sharp sand to keep the whole porous. When potting place a small quantity of sand under each bulb to encourage new roots, and leave about one-third of the bulb above ground. Pot fairly firm, and if the pots are plunged in a warm bed the heat may range from 70 degrees to 80 degrees. Give no water, except with the syringe, until the roots have taken good hold of the soil.

CALADIUMS.—The corms of these fine foliage plants should now be given attention, and to ensure the plants in each specimen being uniform, carefully arrange them in three sizes, large, medium, and small. The practice of starting the corms previous to potting is seldom satisfactory. The compost should consist of good turfy loam and fibrous peat in equal parts, with some not over-decayed leaves pressed through a sieve, and a little spent mushroom bed manure, adding a good proportion of coarse sand. For good specimens use pots large enough to contain sufficient corms, which, when well started, can be shifted into larger pots. Occasional damping with the syringe is all that is necessary for some time. A slight bottom heat is favourable to free development.—W. **Fyfe**, Lockinge Gardens.

FRUITS UNDER GLASS.

EARLY PEACHES AND NECTARINES.—Give plenty of air and keep the house cool until the flowers have set. On a fine day, about half-past eleven, give the trees a sharp rap in order to distribute the pollen. See that the borders do not lack water, and give the house a fumigation as soon as the flowers have set. This should always be done, as sometimes an attack of aphis proves troublesome to eradicate in the early stages, and a gentle or mild fumigation will check an attack. Successional houses may now be closed at nightfall, but give air in the day according to the weather. With increased sunshine the flowers will begin to push, and a second house may be started as close to the first as may be necessary.

EARLY VINES.—Tie up the rods when the shoots are seen to be coming away strongly, and if there are several shoots to one spur thin out the weakest, and give encouragement to those that are left. Tie the rods up with tarred string. In the event of mealy bug having been present last season, there may be a few left in crevices, and these will now, on sunny days, be leaving their hiding place, and should be diligently sought after. This is one of the best times for thorough eradication of the pest, and the vines should be looked over every day, as a man or lad with a small brush and some paraffin can kill a lot in an hour. See that roots near the pipes are not dry. Syringe twice daily and damp the floors, especially in the evening, about seven o'clock.

MUSCAT HOUSE.—The vines, if they have had the cleaning recommended, may now be got ready for starting. The Muscats require a long season of growth to secure the best possible results. If the borders have been cleaned and dressed the house may now be closed and kept at a temperature of 50 deg. Do not allow the temperature to run up high in bright weather or the rods will break quickly and weakly. Muscat of Alexandria requires, perhaps, lighter soil than many grapes, and this should be afforded where new borders are being made.

PROPAGATING GRAPE VINES.—Eyes may be put in now if vines are required. By eyes one means the buds of ripened wood of last season's growth. Cut the eye to about an inch and a-half in length, and place in shallow boxes or pans, or in small pots. I prefer small pots. Use good sweet soil, and place in a propagating frame; keep moist, but not wet. Nothing is so bad for the vine as sour soil in any stages of growth.

MELONS.—These will now be ready for shifting into 5in. pots, from which they should be planted out; use good loam with just a little fine manure. Pot firmly, and place in a light position, as near the glass as possible, and give bottom heat. A second sowing should be made. Blenheim Orange is a fine secarlet-fleshed variety, the fruit being of good size, and it ripens early. A1 is also a fine scarlet-fleshed melon, and Best of All is a good green-fleshed variety, while the old Hero of Lockinge (white flesh) still holds its own. Sow in small pots and place in a temperature of 70 deg.

CUCUMBERS.—Plant out as soon as ready those sown last month. Have the soil in the house several days before being required, so that it will be thoroughly warmed. If no bottom heat exists makes up a small hotbed of manure and leaves, as this will prove of much value in pushing the plants on to the fruiting stage. Keep the house moist by syringing and damping, as dry heat is very fatal to cucumber growing. Continue to clean houses and pits as they become vacant, so that these are ready to receive new and clean occupants. — W. A. **Cook**, Leonardslee Gardens.

THE KITCHEN GARDEN.

CUCUMBERS. — The early plants, if nursed along with attention to potting as required, will be large enough to plant out in the forcing house on hot-beds in hillocks of soil. No better rooting medium for large crops can be had than good heavy loam with a fair quantity of lime rubble and a little soot added to it. Keep a moist atmosphere throughout by damping down the house frequently, and syringe the plants on fine days. Maintain a night temperature of 60 to 65 deg. with 5 deg. higher during the day.

MUSHROOMS.—If the mushroom house is of the usual size, from 25ft. to 30ft. long, a bed will require to be made up at least once a month to ensure a full and continual supply. Collect manure from it into a heap to ferment, and turn it on alternate days until its rankness has thoroughly escaped, after which it will be in a condition to make up into a bed. Should manure be scarce, or insufficient to fill the desired space, a third part of oak leaves may be added to give the needed quantity without in any way reducing the value of the manure. Our best bed this season was so treated. A fruitful cause of failure is spawning the beds at too high a temperature, therefore allow the heat of the bed to decline to 85 deg. before inserting the spawn. Afterwards apply a dressing of about an inch of rather adhesive loam.

ONIONS.—Where large bulbs of onions are desired for special purposes of the Ailsa Craig type, a sowing should be made at once in boxes in a rich open soil. Place them under glass in a temperature of 50 deg., and germination will quickly take place. Keep the young plants near the light, and when large enough, prick them out into other boxes at about three inches apart in good soil; when firmly established gradually harden them off to a light cool frame, admitting air according to the outside conditions until they are large and hardy enough to be planted out towards the end of March or beginning of April.

ASPARAGUS.—This vegetable is always appreciated whenever it can be obtained. Where convenience is at hand it well repays the trouble it entails. In introducing the crowns to the forcing pit, carefully lift them with as many roots as possible, and without exposing them to drying winds during the process. Keep up a temperature of about 55 deg.; water rather liberally with warm water, and syringe the pit often to encourage a moist atmosphere.

GENERAL REMARKS. — This and next month all plants that are under protection in frames will be very liable to damp, therefore take advantage of every fine day to ventilate freely. Endive and lettuce will be specially liable to lose their centres. Remove batches of these to the blanching house according to the call for them. Sow mustard and cress at intervals, and do everything possible to carry over this, the worst season of the year. Tarragon in many places is in request most of the time; lift some roots from the open, and either place them in boxes, or in large pots of soil in a newly-started peach house or vinery. — C. **Flack**, Cholomondely Castle Gardens.

PROPAGATION OF SHRUBS BY LAYERING.

When dealing with species of trees and shrubs that cannot be readily increased by means of cuttings, layering is resorted to, and results in the production of good bushy plants in a comparatively short period. If the work is carefully carried out it is effected without inflicting the slightest injury upon the parent plants. The method may be also recommended with regard to species of slow growth generally, in spite of the fact that these may be readily propagated from cuttings.

The operation is simplicity itself, and can be carried out at almost any time of the year, and, speaking generally, eighteen months to two years must be allowed to elapse before the layers are removed from the parent plants. All the preparation that is necessary, as far as the branches are concerned, is the removal of the side growths and leaves at the most convenient point for bringing a length of clean stem six or more inches below the surface. After it has been decided which growths will be treated,the ground immediately underneath must be deeply dug, a liberal quantity of sandy soil, such as that found underneath the potting bench, being added to each site, when it only remains to bring the branch down and secure it in position in the cavity prepared for it, and ram the soil as firmly as possible over the whole site.

Experience goes to show that where a branch has been partly broken during the process of pegging down, it has formed a much larger body of roots than others that have remained entire, and we gather from this that it is advisable, and a distinct advantage, to slightly split or lacerate the branches, much in the same way as when layering carnations. The labour involved in maintaining the sites in a moist condition during times of drought will be well repaid,and it must be remembered that in many instances rains are carried outside their area. Common sense will also suggest that the rooted layers be removed at a season most suitable for their re-establishment, and there is also much to recommend in the practice of disconnecting them from the parent plants some weeks prior to removal.

The following may be successfully treated in this way: The various pyruses, ceanothuses, magnolias, wistarias, rhododendrons, hollies, the hardy heaths, andromedas, dahpnes, myricas, zenobias, halesias, chimonanthuses, calycanthuses, leucothoes, phillyreas, styrax, etc.

Walter H. Aggett.

Index to the "Gardeners' Magazine," 1908.—Those readers who have preserved the 52 numbers of the Gardeners' Magazine for 1908 with a view to having them bound for future reference, can obtain Handsome Cloth Binding Cases from the publishers, 148 and 149, Aldersgate Street, London, price 2s., post free. The index, with title page, is now ready—price 2d., or by post 2½d. The volume bound complete will also be ready in a few days, price 12s. 6d., by post, 13s. 4d.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

Royal Horticultural Society.

SCIENTIFIC COMMITTEE, JANUARY 26.

Present: Mr. E. A. Bowles, M.A., F.L.S. (in the chair), Dr. A. Voelcker, Messrs. S. Pickering, A. Worsley, E. M. Holmes, G. Gordon, W. Hales, J. W. Odell, and F. J. Chittenden (secretary).

DISEASED CARNATIONS.—Mr. Saunders and Mr. Douglas reported upon the diseased carnations shown at the last meeting that in all probability they had died through attacks of stem eelworm. The soil used for potting was too light, and the plants were too old to obtain the best results from. Plants of two years of age were sometimes liable to sudden collapse, and those of a greater age even more so.

GREASE BANDS.—Mr. Voss reported that no moths had been caught upon grease bands on fruit trees at Enfield since November.

ALGÆ, ETC., ON SEWAGE SLUDGE.—Dr. Voelcker remarked that mosses, hepatics, and algæ had developed upon certain samples of sewage sludge which had been kept at Woburn, but not upon others which were kept under precisely the same conditions. The samples which contained the greatest amount of lime bore the largest amount and greatest diversity of growth, and it was thought that possibly the difference was as much due to the physical condition of the sludge as to its chemical constitution.

SCILLA, ETC.—Mr. Worsley showed an inflorescence of Scilla hæmorrhodalis, a plant with rather inconspicuous flowers, followed by larger fleshy fruits. He also remarked upon the inconstancy of the arrangement of the spines in certain of the cacti in various stages and at different ages, and stated that in his opinion the arrangement of the spines constituted an insecure basis for the classification of this family.

FASCIATION.—From Sir Trevor Lawrence, Bart., came a fasciated specimen of anthurium bearing two spathes and spadices. Mr. E. H. Jenkins sent a fasciated specimen of Daphne japonicum.

ODONTOGLOSSUM MALFORMED. — A flower of an odontoglossum having three stamens and a much-reduced perianth was received from Mr. Gurney Wilson, and referred to Mr. Saunders for further examination.

VARIATION IN FOLIAGE OF CYCLAMEN.—Mr. Bowles showed a large number of leaves of Cyclamen hederæfolium from his garden exhibiting great and wide variation in the arrangement of the markings upon the foliage, especially in the extent of the whitish margin and median blotch which is usually present. He found the variations to be characteristic of and retained by the individual plants.

National Chrysanthemum Society.

There was a fairly good attendance at Essex Hall, Strand, W.C., on Monday evening, February 1, on the occasion of the annual meeting of the National Chrysanthemum Society, when Sir Albert K. Rollit, president of the Society, presided. The business was put through with despatch, and as no controversial matters were brought forward the meeting concluded within the hour.

After the usual formal business the annual report and financial statement, copies of which had been sent to all members, were taken as read. We append these in abridged form

REPORT OF THE COMMITTEE FOR 1908.

It gives your committee great satisfaction to be able to report that Sir Albert Rollit, D.C.L., LL.D., was, at the annual general meeting of members held in February last, elected president on the retirement from that office of Charles E. Shea, Esq. At the same meeting Mr. Shea's name was added to the roll of the society's vice-presidents.

The grand autumn show, which was opened at the Crystal Palace on November 4, marked a distinct improvement on previous years in its general effect, chiefly by reason of the fact that the whole of the North and South Naves, together with part of the Central Transept, were available for the society's purposes for the first time since our shows have been held at Sydenham. The increased accommodation thus afforded gave opportunities of a much more effective display, and public and Press were alike of opinion that those opportunities had been utilised to the fullest extent.

The dates of the shows for the current year have been provisionally fixed for October 6 and 7, November 3, 4, and 5, and December 1 and 2.

The meetings of the Floral Committee have again been an important feature of the society's work during the past season. The committee met on seven occasions to consider new varieties, three times at the Crystal Palace on the opening days of the shows, and four times at Essex Hall; 250 entries were recorded during the year, as against 215 in the previous season, and awards were made as follows: 47 First Class Certificates, and 2 Commendations. In the case of every variety submitted the colour is carefully determined and recorded. and several difficult cases of classification were settled by the committee during the season. Mr. D. B. Crane again undertook the duties of chairman of this committee.

Arrangements have already been made for the 1909 outing, to be held on August 9 next, when a visit will be paid to the world-renowed gardens of Sir Frank Crisp, at Friar Park, Henley-on-Thames.

Seventy-two new members were added to the society's register during the year, namely, ten Fellows subscribing £1 1s. per annum, fourteen ordinary members subscribing 10s. 6d. per annum, and forty-eight ordinary members subscribing 5s. per annum. The increase is mainly due to the personal efforts of the President of the society. Six societies applied for affiliation during the twelve months, and were added to the society's roll.

The dates for the meetings during 1909 have been fixed as follows: Executive Committee, September 20, October 25, November 15, and December 13; Floral Committee, September 20, October 6, October 25, November 3, November 15, December 1, and December 13.

STATEMENT OF ACCOUNTS.

RECEIPTS.

To Balance at Bank brought forward	£21	11	11
Subscriptions	171	11	2
Donations and Special Prizes	51	6	0
Crystal Palace Company—December Show, 1907	25	0	0
Entry Fees, 1908	15	2	6
Affiliation Fees	53	0	6
Medals, etc.	81	9	9
Catalogues Sold	0	17	11

Insurance of Trophies	1	1	3
Crystal Palace Co. (Proportion of Space Charges, 1907)	4	8	2
Balance of Petty Cash	2	10	1
Balance at Bank	111	4	8
	£512	3	9

Liabilities amount to £306 16s. 3d. and assets to £409 15s., leaving a surplus of £102 18s. 9d.

Sir Albert Rollit moved the adoption of the report and accounts, and referred to the brilliance of the society's exhibitions, the international associations of the society, the work of the various officers, the special value of the Floral Committee's proceedings, the economy effected throughout the year, and the increase of membership. He also pointed out that all special prizes had been paid, and he hoped that in a few days the balance due from the Crystal Palace Company would be paid in, so that the rest of the prize money could be at once paid. The motion was seconded by Mr. Thomas Bevan, and carried without comment.

The auditors were thanked for their service, and, amid loud applause, Sir Albert Rollit, on the motion of Messrs. Simpson and Witty, was re-elected president. Messrs. Moorman and Hemsley proposed the re-election of Mr. John Green as treasurer, and this was heartily carried. Mr. Thomas Bevan and Mr. E. F. Hawes were re-elected chairman and vice-chairman respectively, and Mr. C. Harman Payne was re-elected hon. foreign corresponding secretary for the twenty-first successive year. On the motion of the President, seconded by Mr. Moorman, Mr. Richard Witty was unanimously re-elected secretary. Messrs. J. Lake and W. H. M. Dean were appointed auditors for the ensuing year, and Messrs. Riding, Cragg, and Prickett were elected scrutineers of the ballot for the election of twelve members of committee, but their services were not required, as nine members eligible for re-election, and only three others were proposed, so that a ballot was not necessary. The members elected were Messrs. J. Emberson, R. F. Felton, A. Hemsley, D. Ingamells, E. Jones, F. S. Oliver, R. E. Reeve, G. Springthorpe, W. Wells, J. B. Riding, H. Runciman, and C. Noyce.

On the motion of Messrs. C. H. Curtis and D. B. Crane, a hearty vote of thanks was accorded Sir Albert Rollit for presiding, and the proceedings then closed.

Reading Gardeners' Association.

The first meeting of the present session was held in the Abbey Hall, on Monday, the 25th inst., and Mr. A. F. Bailey, the recently-elected chairman, who presided, was welcomed by a large gathering of members.

The lecturer for the evening was Mr. J. W. Odell, The Gardens, The Grove, Stanmore, and his subject "British Wild Flowers in the Garden." Mr. Odell illustrated his paper with a comprehensive and beautiful series of photographic slides, and the appearance of these pictures on the screen provoked frequent and hearty applause, for it must be confessed that to many professional gardeners (to say nothing of amateurs), it was a revelation that the wild flora of the British Isles contained so many charming subjects, the lecturer remarking with reference to some of his particular favourites, that if they had to be imported from The Himalayas or Japan, they would not be allowed to "blush unseen."

Many beautiful illustrations of hard-wooded plants, in bloom, were first shown on the screen, including the wild cherry, lovely in spring as well as in late autumn, crab, plum, dog rose, etc. These were followed by equally lovely pictures of British aquatic and bog plants, rock, woodland, and climbing subjects, and finally the lecturer dealt with the small but fascinating family of British orchids.

It was pointed out by Mr. Odell that failure in the wild garden was frequently the result of scanty knowledge of the subject, and he showed how important it was that if wild flowers were cultivated it should be under conditions as nearly as possible like those in which the collector found his specimens. For the common harebell, it was perhaps difficult to find an uncongenial situation, but for the Orchis family the natural habitat of the plant must be carefully studied.

In conclusion, the lecturer deplored the robbing of our streams, hedgerows, and woods by unscrupulous vendors, which was likely to be the means of killing many lovely subjects, and he urged his hearers to discourage such ruthless destruction by refusing to purchase from itinerant hawkers of ferns, etc.

Only a short time remained for the discussion, but to the questions put by Messrs. Tunbridge, Stanton, Exler, Loader, Dore, etc., the lecturer readily responded. A hearty vote of thanks to Mr. Odell for his excellent lecture was proposed by Mr. Alderman Parfitt (president of the association), and carried with acclamation. Several new members were elected.

Bristol Gardeners' Association.

Mr. S. Shaddick presided over a large attendance, on Thursday, January 29, at St. John's Parish Rooms, when the representative of the Bath Gardeners' Debating Society, in the person of Mr. Stokes, of Trowbridge, gave a very able and comprehensive paper upon "Rock and Alpine Plants." The lecturer said there was no place in the garden so gladdening or refreshing as the rockery. The plants are natives of such extreme climates as the tropics and the Alps, and this fact must be taken into consideration when building a rockery, and provision made for all. Where possible build ledges, nooks, dells, and caves, and if water is obtainable a channel can be made for the water to trickle down between the stones, so that moisture-loving plants may luxuriate in as natural conditions as possible. A hearty vote of thanks was accorded to the lecturer at the close. For a dish of culinary apples Mr. J. Scott was first, and Mr. Attwell was second.

Liverpool Horticultural Association.

The thirtieth annual general meeting of this association was held on the 31st ult., Mr. Thomas Foster presiding. The report and statement of accounts were read, and approved. Owing to the depleted exchequer it was arranged that only one—the autumn—show should be held last year, with the result that the balance of £52 17s. 8d. at the commencement of the year has increased to £170 15s. 3d. The chief items of income were the subscriptions, £254 5s. 6d.; admissions to show, £110 1s.; special prizes and entrance fees, £19 13s. Payments: Prize money, £114 11s.; hire of hall, £37 16s.; printing and stationery, £39 8s. 3d.

In considering the current year's programme, some discussion took place with regard to a spring show, but it was decided that it should not be held this year, but that the committee would consider the desirability of holding a limited summer show, in which sweet peas and roses would be the prominent features. Mr. G. Blackmore, treasurer, and Mr. Harold Sadler, secretary, 31, North John Street, Liverpool, were reelected.

Professional Gardeners' Lodge

(BRANCH 6,776 OF THE GRAND UNITED ORDER OF ODD-FELLOWS).

The following report has been sent us, but we do not gather when the annual meeting was held:

In submitting to you the forty-second annual report and statement of accounts, your committee congratulate you upon the progress made during the past year. The sickness experience has again been favourable, and although the claims have been somewhat heavier than they have been during the past few years, still, they are considerably below the expectation. Sixteen members have received sickness benefits during the year, the total amount paid to them being £71 0s. 10d. £20 has been paid in funeral allowances, making the total amount paid out of the benefit fund £91 0s. 10d. This fund now amounts to £1,564 13s. 11d., an increase during the year of £82 2s.

The management fund still remains at £50, all sums above this amount being transferred to the benefit fund, as per Rule 21. The sum of £6 15s. 2d. has been so transferred this year, this is due to the substantial support so generously given by the honorary members, and to the economical management of the lodge. The amount of the distress fund is £3 3s. 4d., an increase of £1 6s. 2d., making a total increase in the whole of the funds or total saving for the year of £83 8s. 2d. The trustees have withdrawn £200 from the bank and invested it with the Leeds Corporation at 3¾ per cent. Fifteen new members have been made, two have died, and three left, the present number being 147, an increase of 10. The committee are sorry to have to report the death of two honorary members, viz., Mr. E. J. Batchelor and Mr. C. Brotherton, their influence and kind interest in the lodge will be much missed.

At the annual dinner on February 12 Bro. George Bumby (the present Grand Master), on behalf of the members, presented to Bro. James Inman, N.G., a framed Emblem of the Order, as a token of their appreciation of the long and valuable services he has rendered to the lodge. These services have been very much missed during the past few months owing to Bro. Inman's serious and protracted illness. The committee, on behalf of the members, desire to express their sympathy with him, his wife, and family, and trust he will soon be restored to his usual health.

ARTHUR EDEN, V.G.
G. CARVER, Secretary.

December 31, 1908.

Oxford Chrysanthemum and Fruit Society.

The forty-sixth annual general meeting of members was held on January 25, at the New Inn Hotel. Mr. T. E. Jefferies, presided, and there were also present nearly thirty subscribers. In the annual report (a copy of which, with the accounts, had been sent to every member) reference was made to the peculiar season of 1908, which caused a smaller entry of blooms through damping off; still, at the show held on November 10, a fairly high quality was manifest in the bulk of the exhibits. Regret was expressed at the falling off in the attendance during the evening hours—a consequence of unemployment of the wage earners, who usually crowd the November exhibitions. The accounts showed that the payments (including £58 as prizes) had exceeded the income by £11 13s. 8d., the society's reserve standing at £13.

Harvey du Cros, Esq., Howbery Park, Wallingford, was re-elected president; Montague Wootten, Esq., treasurer; W. F. Cross, Esq., hon. secretary; Mr. W. Greenaway, acting secretary (forty-first year); Messrs. W. Balmforth, J. S. Chidlow, F. Harris, J. Johnson, S. Mold, W. R. H. Powell, W. E. Reynolds, H. Smart, and J. C. Tayler to compose the Committee of Management.

It was arranged that owing to the Municipal Buildings being occupied during the first half of November, the next show should be held on October 28.

Cardiff Gardeners' Association.

At the recent fortnightly meeting of the above association, Mr. H. R. Farmer presiding, a lecture was given by Mr. F. Woods, head gardener at Llanfrechfa Grange, Newport, on the "Madresfield Court Grape." The lecturer, in his opening remarks, stated that, in his opinion, this variety can be as successfully grown as the Black Hamburgh or any other ordinary kind, and he failed to understand why it was not more generally cultivated, as it was considered one of the finest flavoured grapes in cultivation. He had successfully grown this grape for many years, and had escaped the berry splitting which is a general complaint respecting this grape. This, Mr. Woods explained, was due to the treatment he adopted. The formation of vine borders, their depth, composition of soils, ventilation, pruning and mulching were clearly explained, and the members listened with keen interest to the lecturer.

Mr. Julian opened the discussion, and remarked on the able manner with which the lecturer had dealt with his subject. Other members took part in the discussion, in the course of which there were many reminiscences of grape growing in bygone years in South Wales. Mr. Malpass proposed, and Mr. Mayne seconded, a hearty vote of thanks to Mr. Woods, who suitably acknowledged, thanking the members for their appreciation.

Birmingham Gardeners' Association.

At the initial meeting of the spring session, held on January 25, there was a good assemblage of the members to hear the chairman of the society, Mr. Thomas Humphreys, curator, Botanical Gardens, Edgbaston, who was scheduled for an essay on "Roses for Suburban Gardens," illustrated with lantern slides. The vice-chairman, Mr. C. H. Herbert presided, and remarked that it was needless for him to introduce Mr. Humphreys as an expert who would not fail to ably demonstrate the subject in question.

After expatiating upon the history and illimitable beauty of our national flower, the essayist gave a graphic and practical demonstration on the cultural requirements of several kinds of roses, according to their nature and suitability for certain sites and purposes, but chiefly in regard to those kinds and varieties adaptable for smoky localities similar to that of Birmingham and its immediate environs. The attention of the audience was also rivetted on the display of lantern slides illustrative of cut blooms, vases of roses, weeping roses as standards, pergolas, arches, etc.

At the conclusion of the address, owing to the lack of time, only a brief discussion ensued, in which Messrs. Herbert, A. R. Brown, and Wm. Gardiner took part, the latter adverting to a few old-time roses known by him sixty years ago, such as, for instance, Devoniensis, the old moss rose, the Austrian Briar, the Scotch Rose, the York and Lancaster rose—all of which were old favourites—and Fortune's Yellow. On the proposition of Mr. C. R. Brown, seconded by Mr. G[illegible] Giles, a hearty vote of thanks was accorded Mr. Humphreys.

A REALLY RELIABLE REMEDY FOR PEST-RIDDEN GARDENS.

No soil insect pest that preys upon plants can withstand the deadly fumes given off by

"Kilogrub"

"KILOGRUB" is sudden death to all pests of the soil. All you have to do is to distribute it well over the ground and work it into the soil, only two or three ounces being necessary for a square yard.

Thorough tests have proved "KILOGRUB'S" worth. Hundreds of experienced gardeners know its value.

Headington Horticultural.

The twenty-eighth annual meeting of cultivators was held in the large room at the British Workman Institute, on January 29. James H. Morrell, Esq., presided over a large attendance. The report referred to the well-kept allotments in the parish, the president's premier award going to Thomas Cross (mason), whose plot reached the standard of 100 points; and also the front garden of Alfred Morris (labourer), who secured another champion award. The reference to the show held on August 3 last included a meed of praise to the dual display of roses on 50 feet space by the brothers J. R. and W. T. Mattock, who set up very fine collections, which in each case secured a gold medal award. The accounts showed a gain of £6 17s. on the year. The chairman, commenting on the allotments, observed that horticulture should be encouraged, and referred to the fact that near Reading they had an experimental garden on the French system, where three crops per year were raised, the result of thorough feeding and minute detail. He hoped to be able to visit Headington allotments during the coming season. Mr. Morrell was re-elected president; Mr. R. H. Dockray, treasurer; and Mr. W. Greenaway, secretary (twenty-ninth year). August 2 was fixed as the date of the next show.

Aberdeen Chrysanthemum Society.

The annual general meeting of this society was held in the hall of the Young Men's Christian Association, Aberdeen, on Saturday evening, January 30. Mr. Andrew Davidson, chairman of the society, presided. Mr. M. H. Sinclair, secretary, read the report for 1908, in which the annual exhibition of the society, held on November 27 and 28 last, was characterised as a good one. The aggregate entries showed a decrease on the previous year, but this was largely confined to the vegetable section. The cut chrysanthemums were very fine, the displays of decorative and single varieties being by far the finest ever seen in Aberdeen. The pot plant section was excellent, and superior to anything shown for years.

The financial statement was not so favourable as could have been desired, but the weather on the second day of the show was exceedingly wet and boisterous, and told disastrously on the gate money. The loss on the year was £29 5s. 10d., but, given more favourable weather, the hope was expressed that this will be more than made good this year. The total income of the society was £300 5s. 6d., and the expenditure was £204 2s. 10d., leaving a balance in favour of the society of £96 2s. 8d.

The report was unanimously adopted. Office-bearers were then elected, the majority of the posts being filled by the old holders, including that of secretary, which is again held by Mr. M. H. Sinclair, F.R.H.S., whose devotion to the interests of the society has contributed in no small degree to its past success.

CATALOGUES RECEIVED.

DICKSONS, CHESTER.—An excellent catalogue of vegetable and flower seeds from the long-established Chester firm. Garden tools and sundries are freely illustrated in it.

HARRISON AND SONS, LEICESTER.—This useful wholesale catalogue of flower and vegetable seeds is freely illustrated, and contains useful tables for planters, etc.

H. N. ELLISON, BULL STREET, WEST BROMWICH.—An admirably-arranged catalogue, in which the finest types of flowering plants usually raised from seed, and vegetables have a place.

DICKSON, BROWN, AND TAIT, CORPORATION STREET, MANCHESTER.—Though not over large, this catalogue of garden seeds is one of the most attractive we have seen: the illustrations are very beautiful.

JAS. BACKHOUSE AND SON, LIM., YORK AND LEEDS.—A good list of garden seeds, including several novelties in flowers and vegetables. Freely illustrated.

JOSEPH BENTLEY, LIM., BARROW-ON-HUMBER.—This is a useful garden diary for 1909 rather than a trade catalogue, though [illegible] the firm's specialities in insecticides, weed killers, etc., are listed and priced. The book is well bound.

THOS. S. WARE, LIM., FELTHAM.—A catalogue of all the most useful vegetables and beautiful flowers, and also a separate catalogue of the splendid tuberous begonias that are the firm's great speciality.

NEW BOOKS.

◆

AN ARTIST'S GARDEN.

By Anna Lea Merritt. (George Allen and Sons, 156, Charing Cross Road, London). Price 21s. net.

The author of this charming book is well-known to the art-loving people in England and America as the painter of the justly famous picture "Love Locked Out," purchased for the nation under the Chantrey Bequest. Mrs. Merritt, while engaged in work that has placed her name high among contemporary artists, has devoted a considerable share of her attention to her garden, which, as the result of her loving care, has become one of the most beautiful of its kind in the country. She has not only made and tended this delightful pleasaunce herself, but she has painted a considerable number of the chief features, and of these sixteen have been reproduced in colours and utilised in the illustration of her book. These illustrations present a striking contrast to many that have come under our notice within a quite recent period. They are not mere splashes of colour, but pictures representative of artistic skill of a high order, with sufficient detail to enable those who know anything of flowers to at once recognise the plants depicted, without being unduly burdened with detail.

The book contains much that is useful as well as beautiful, and amateurs will have no difficulty in obtaining much information of value, more especially in the creation of distinct effects. More especially would we commend to their notice the list of plants in various colours, and for different situations, as from this they will be able to obtain useful advice on the pictorial possibilities in the arrangement of a garden. As a book for the drawing-room it has but few equals, for while unsurpassed for the extreme beauty and interest of its illustrations, the reader will be able to obtain many suggestions for the artistic arrangement of the plants that usually have a place in the flower garden.

FRUIT TREES AND THEIR ENEMIES.

By Spencer Pickering, M.A., F.R.S., and F. A. Theobald, M.A. (Simpkin, Marshall, Hamilton, Kent, and Co., London). Price 1s. 6d. net.

The enemies of fruit trees are many, and so destructive when allowed to commit their ravages unchecked that it is not less necessary cultivators should be acquainted with their habits, and the best methods of keeping the trees free from them, than it is they should be acquainted with soil preparation, pruning, and other details of successful culture. The book now before us is a valuable aid to the acquisition of a knowledge of the enemies of fruit trees, and the best methods of preventing attacks, and of annihilating such pests that may have been able to become established. It is, therefore, especially welcome, and the authors have rendered a service that could not well be overestimated in placing their store of information at the disposal of fruit growers in so concise and otherwise admirable a form.

REPORT ON THE WOBURN EXPERIMENTAL FRUIT FARM.

By the Duke of Bedford, K.G., F.R.S., and Spencer U. Pickering, M.A., F.R.S. (The Amalgamated Press, Carmelite Street, E.C.). Price, 2s. 6d.

This, the ninth of the series of reports on the work that has been carried on at the Woburn Experimental Fruit Farm, contains much that should have the instant attention of those who are engaged in the cultivation of hardy fruits. This issue is wholly devoted to a report on the results of the series of experiments in planting which included ramming the soil in planting operations, plastering roots, planting in sand, deep planting, trenching the ground, influence of the date of planting, behaviour of trees after planting, and the arrangement of trees in planting. In a recent issue we directed prominent attention to the results obtained in ramming the soil, and we would here add that the results obtained in the other planting experiments are not less remarkable and interesting. In the appendix to the report there are two important papers by Mr. Pickering; one is devoted to "Studies on Germination and Plant Growth," and the other to "The Action of Heat and Antiseptics on Soils."

THE SWEET PEA ANNUAL.

Edited by C. H. Curtis and H. J. Wright. (C. H. Curtis, Adelaide Road, Brentford.) Price, 2s. to non-members.

The high character of the official organ of the National Sweet Pea Society is fully maintained in the issue for the current year. The contents include "Mendelism as Applied to Sweet Peas," by Mr. W. Cuthbertson, who for several years past has been engaged in the practical study of Mendelism in the garden with the aid of sweet peas; "Sweet Peas in Pots," by Mr. Edward Teschemacher; "Winter-flowering and Early Sweet Peas," by Mr. Charles Foster; and a "Colour Chart for Sweet Peas." There are numerous other articles, and also audits of the London and Dublin shows, reports on the visits made to the trial grounds at Reading, Kelveden, and Mark's Tey, and articles. The annual is freely illustrated, and the illustrations include a goodly number of portraits

Apricots.—The spurs soon become elongated and crowded, unless we remove some of the oldest and shorten a few of the others each season, endeavouring to keep the remaining spurs as close to the wall as possible. It is advisable to reserve a few well-placed young growths each season to take the place of those branches which, from no apparent cause, suddenly die off, or for those which become worn out. Very few insect pests are in a usual way found to infest the apricot; the most troublesome which we have had to deal with is the caterpillar of the Apricot Moth (Tortrix angustiorama), which feeds on the young leaves. Their presence may be easily detected by the curling of the leaves. A few minutes each day is well spent in examining the trees as the foliage develops, destroying any pests that may be found by pressing the curled-up leaf between the finger and thumb.—G. Woodgate.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

SEED TESTING. — G. E., Spalding: Do you mean a place where the germinating power of seeds could be tested, or where the plants could be grown from seeds and flowered to show their purity of strain and fixity of character?

DOUBLE-SPATHED ARUM.—G. F., High Wycombe: We have specimens of double-spathed arums sent us several times each year, and sometimes greater curiosities than these, for the arum, under high cultivation, appears inclined to go beyond the limit of its usual method of producing an inflorescence. It must be remembered that a spathe approximates closely to a leaf, and that leaves show considerable variation one from another, even on the same branch of a tree. It is generally believed that the production of one or more small spathes in addition to the normal one is the result of unusual vigour on the part of the plant, produced, probably, by high cultivation. It is interesting to learn that the same plant has produced a double-spathed inflorescence two years in succession; if the variation proves to be so fixed that plants propagated from it also give twin-spathed heads, it will be the more interesting.

CYCLAMEN BUDS FAILING TO EXPAND.—A. S., Guildford: Some grub or weevil has evidently taken a liking for the roots of the young cyclamens and eaten off a considerable number, so that when the developing flower buds made a strong demand upon the roots for nourishment, the demand could not be met. What actually caused the damage we have no means of knowing, as all soil was shaken from the plant sent. Carefully examine the soil in the pot containing a similarly affected plant, and you will probably find some grubs of the vine weevil.

MANURING EVERGREEN SHRUBS.—M. C. D., Surbiton: It is very rarely that we are asked to advise with reference to manuring evergreen shrubs. There is no doubt whatever that many fine evergreens, notably conifers, have been lost, or spoiled, for lack of feeding, and a manurial dressing occasionally would have saved them. If the shrubs do not make good growth, then by all means give the border a dressing of manure, forking it in lightly. The dressing may be given at any time now when weather permits. Aucubas and laurels grow so freely, as a rule, that the difficulty is to keep them from overcrowding and spoiling other and better subjects. What else have you in the border? If you will tell us we may help you to improve it.

CARNATIONS WITH BURST CALYCES.—J. W. L., Liverpool: Winter-flowering carnations vary a good deal in the matter of split calyces. Some varieties produce very few blooms that come to perfection with an entire calyx, while other varieties rarely have a split calyx. So far as we can gather your method of cultivation is correct, but the possibility of damage done by a sudden and severe change of temperature must not be overlooked. We have seen a good deal of harm done in a few hours, when, in anticipation of a severe frost, heat has been turned on considerably, and then a sudden change in the outside temperature has occurred. You do not say what varieties of carnations you grow, or whether all varieties show the same failing. Small rubber rings would reduce the failure if the majority of the blooms reached a more advanced stage than those sent before bursting.

TIMING CHRYSANTHEMUMS.—H. J. J., Norbiton: We have frequently dealt with the subject of "timing" and "bud-taking" in these columns, but, until you are familiar with the procedure it will be worth while having a handy reference book on the subject at hand, such as "Chrysanthemums and How to Grow Them for Exhibition"—1s. 2d., or 1s. 8d. (cloth bound), from the GARDENERS' MAGAZINE Office, 148, 149, Aldersgate Street, E.C. With this at hand, and a regular perusal of our calendar notes and special articles dealing with chrysanthemums, you will have no difficulty in producing good blooms.

PERGOLA FOR A SMALL GARDEN. — G. S. E., Ryhall: In the construction of a pergola in a moderate-sized garden, the width from post to post should be about eight feet, and on either side a space of about ten feet should be allowed between the uprights. When these have been secured, fixed in position, they should be tied together with cross pieces rather less in thickness than the uprights, and if of the same kind of wood, it will be preferable. The larch and oak uprights should be about five inches in diameter, and those of deal be about four inches square, and the cross pieces of the latter be four by three inches. To preserve the wood used as uprights for as long a period as possible, about three feet of the lower portion should be creosoted or treated with some preservative. The path beneath the pergola may be of gravel or thin flagstones, but the latter are preferable. If the latter are used allow a space of two or three inches between them, and in the spaces thus formed mossy saxifragas, sedums, and other plants of lowly growth that will not suffer materially from being trodden upon, may be planted.

PRUNING CRIMSON RAMBLER ROSE.—M. M. B., Exeter: Some of the old growths that had finished flowering should have been cut out last season to afford more room and light for the new growths then being produced. In March, shorten the long growths made last year, cutting some of them back considerably, so as to furnish the base of the pillar. Many of these growths will have lateral growths, but these latter should not be pruned at all.

ERADICATION OF COLTSFOOT. — L. N. D., Woking: Quite recently the Board of Agriculture carefully investigated the whole subject of the prevention of and cure for a coltsfoot invasion. The weed is a quite common one, but very frequently no attempt is made to get rid of the pest until its conspicuous broad leaves become an eyesore. It is, however, essential to check seeding, and the plant should be spudded or hoed out while in flower (February and March). This prevents the mischief due to the distribution of ripe seed, and if properly done many of the leaf buds on the root-stock just below the surface of the soil are damaged, weakened, or destroyed at the same time. Repeated spudding or hoeing of the leaves must be practised early in the season, and also later in the year. The practice is especially necessary where the plant is established on arable fields. Wherever possible the ground should be dried by well-placed drains. The plant does not succeed except where the soil is stiff and retentive of moisture. Coltsfoot grows best, and is especially adapted to thrive, in situations where the leaves have free, unrestricted exposure to sunlight. Hence it succeeds on poor soils where other plants are checked, the absence of competition favouring its access to light. On arable land kept free from other weeds it luxuriates especially. In pastures and meadows it can be gradually destroyed by the application of manures of a nitrogenous character—farmyard manure, nitrate of soda, and similar materials—which encourage grass and other tall-growing herbage. Deep ploughing in the hotter periods of summer does much to destroy it.

DESTRUCTION OF VERMIN. — Most gardens are pestered with Rats and Mice. Every effort should be made at this time of the year to exterminate them before seeds are sown. Danysz Virus is first rate stuff for killing these vermin. Single tube, 2s.; three tubes, 5s. Post free from DANYSZ VIRUS LTD., 52, Leadenhall Street, Garden Dept., London, E.C.-

WILLIAM BULL AND SONS, Warrant Holders to HIS MAJESTY THE KING, King's Road, Chelsea, London, S.W.

A SPLENDID NOVELTY.
WEBBS' NEW GUARDIAN POTATO.
3s. 6d. per peck; 12s. per bushel.
From Mr. E. Beckett, Head Gardener to Hon. Vicary Gibbs, Aldenham House, January 11, 09.—"You will be glad to hear that your new Guardian Potato proved to be the heaviest cropper by far, and the best disease-resister we grew during the past year, 1908; the only variety which exceeded, weight per acre, the Scotch and Irish grown seed. It is unquestionably one of the very finest main crop potatoes yet raised. I have deferred writing as to its merits till now, as I was anxious to test its keeping qualities, which are all that can be desired. I intend to plant it very largely during the coming season."

WEBB and SON, The King's Seedsmen, WORDSLEY, STOURBRIDGE.

LAXTON'S FRUIT TREES and STRAWBERRIES.—Thousands of beautifully-trained trees to select from in all shapes. Fully illustrated Catalogue post free. LAXTON BROTHERS, Fruit Specialists, Bedford.

SOW NOW UNDER GLASS.
SUTTON'S SUPERLATIVE MELON.
Per packet, 2s. 6d., post free.
Mr. A. Goedecke, gardener to J. Ferguson Pullar, Esq., writes: "I had a grand crop of Sutton's Superlative Melon. I think this is the best Scarlet Melon in existence; it sets freely, even in a frame. I won First Prize at Perth against a very strong competition."

SUTTON AND SONS, THE KING'S SEEDSMEN, READING.

NOW IS THE TIME TO PLANT (the best time of the whole year)
KELWAY'S BEAUTIFUL BLUE DELPHINIUMS.
Hardy, and flourishing in every garden, they are the STATELIEST of PERENNIAL PLANTS for borders or beds; these celebrated improvements are invaluable for their introduction of that precious colour—blue—in masses to the garden. KELWAY and SON developed this race, and they should be procured direct from the Royal Horticulturists, Langport.

KELWAY'S IMPROVED DELPHINIUMS are now ready, strong plants, in choice named selections. Collection "B," 15s. per doz. Collection "D," 42s. per doz. Delivery free for remittance with order. KELWAY and SON, The Royal Horticulturists, Langport, Somerset.

THE DASHING BEAUTY OF THE PÆONIES.
To secure a show this year the planting of Kelway's lovely new Paonies should not be delayed much longer. Really strong plants, full of bud, are ready now of Kelway's celebrated named kinds in collections as follows:—
Collection "B," 21/- per dozen; 50 for £4.
" "D," 36/- " "
Everything free for remittance with order.
KELWAY and SON, The Royal Horticulturists,
Langport, Somerset.

FRANCO-BRITISH EXHIBITION, 1908
ONE of the ONLY THREE Gold Medals or Higher Awards, open to the whole world for permanent exhibits awarded by the International Jury, and confirmed by the Governing Council was awarded to Kelway and Son: vide the AUTHORISED LIST published in the Press. KELWAY and SON, Langport, Somerset.

FOR PRESENT PLANTING.
PLANTERS of FRUIT TREES should write for our fully descriptive catalogue and supplement, 6d., post free; and gratis to customers.
Well-ripened trees of all kinds, and our large, developed specimens of Vines, Figs, Peaches, and Nectarines, are especially good.
An inspection solicited.
GEORGE BUNYARD AND CO., Ltd.
The Royal Nurseries, MAIDSTONE.

TO-DAY! AND FOR YEARS AND YEARS PAST the XL ALL Specialities are and have been the best on the market. Where is the Gardener who does not pin his faith to one or the other of these celebrated Insecticides or Fertilisers? XL ALL FERTILISER has pleased all who have used it this season. The Sales of XL ALL FUMIGATOR prove that it is more popular than ever. XL ALL LIQUID NICOTINE INSECTICIDE is always spoken of by gardeners and growers as the most deadly to Mealy Bug, Thrip, etc. XL ALL WINTER WASH for dormant Trees acts like magic, clearing the Trees and Bushes of all Insects' Eggs, Moss, and Fungoid Growths. XL ALL LAWN SAND, a weed eradicator and fertiliser for weedy and poor lawns. XL ALL WEED KILLER used once a year "No weeds can live." Please ask your Nurseryman, Seedsman, or Florist for a copy of my small pink list, giving particulars of these and many other XL ALL Preparations, which can be obtained from the Horticultural Trade throughout the World. G. H. RICHARDS, Manufacturer and Patentee, 234 Borough High Street, London, S.E.

Sutton's Record Improvements in Peas.

During the long History of our Firm the new strains of Vegetables introduced by us have increased the quantity, improved the quality, and extended the duration of all kinds of garden produce; and the results of unremitting labour have never been more apparent than in the New Varieties we now offer.

In Garden Peas especially, we have by cross-breeding and selection secured such marvellous developments, that, under suitable cultivation, Marrowfat Peas of exquisite flavour are now available as table delicacies from May to November, and the handsome pods win Premier Honours on the Exhibition stage.

DELICIOUS MARROWFAT PEAS

NOTES OF THE WEEK.

Vegetable Avalanches.

The recent bog-slides in Ireland, accompanied as they were by loss of life and the destruction of property by the burial of both dwellings and associated cultivated land under many feet of mire, constitute curious examples of sudden natural catastrophes due to the gradual accumulation of material on insecure foundations. The avalanches common to alpine regions owe their occurrence to the accumulation of snow on more or less accentuated slopes, with the result that the weight eventually leads to the detachment of the mass from the rock beneath; the bog slide, on the other hand, is due to a very different cause. Here we have possibly a very gentle slope, covered by a mossy peaty coat of considerable depth. Here and there hollows occur, in which water accumulates, and in this water, year after year, and it may be decade after decade, aquatic or subaquatic vegetation flourishes, consisting mainly of sphagnum and other mosses with associated bog plants, most of which has a continuous surface growth, while beneath the old foliage and the roots decay and build up the dark brown mass known as peat. The result is that in the hollows what are practically enormous sponges are formed, invading constantly more and more the retaining banks, themselves nothing more than somewhat solider peat. Obviously, this cannot be continued indefinitely, and sooner or later an extra wet season comes, the sponge is saturated to the utmost, the retaining banks themselves become waterlogged and softened, and finally, at some weak point, an outlet is formed, and the great bulk of the imprisoned mass spreads by the mere force of gravity over the lower levels carrying devastation, and probably death, in its wake. A more insidious invasion than a bog slide can hardly be conceived; unlike the alpine avalanche, with its thunderous reverberations, it may be perfectly noiseless. Not a sound is heard but the pattering of the raindrops which have determined the culmination of gravitational force which has brought down the silent flood of oozy black mud and spongy debris, the presence of which at the very doors of the invaded cottages is only known when they are opened and the flood rushes in precluding all escape. There is, however, still another difference between the two catastrophes, the one is preventable, the other not. Year after year these calamitous bog slides occur; the localities subject to them are, or ought to be, well known; that their genesis is due simply and solely to a lack of drainage is equally well recognised, and yet they are permitted to occur. A still more important fact, and one which at this moment should not be lost sight of, is that all this peaty land was once forest land, and could be restored once more to forestal conditions. The unstable conditions of a peat bog are due to the absence of any such binding factors as the roots of larger vegetation afford. The very accumulation of the water is partly attributable to absence of arboreal roots capable of absorbing it and utilising it, and of arboreal foliage which would transpire it, and by its formation of valuable timber transform, at the same time, these poverty-stricken districts into areas of profitable industrial employment. That in a country like Ireland immense areas are practically waste, so that emigration is considered the only way of keeping alive in many parts of the country, is nothing less than a national disgrace, which such attendant calamities as we are treating of emphasise. Abroad there exists abundant evidence how the question of afforestation can be dealt with; the climate is in its favour now, as it must have been in the old forestal days of the pre-bog period. The recent report of the Commission appointed to study this question is all in its favour, but the main obstacle appears to be in the lack of the spirit of farseeing enterprise necessary for national work involving present outlay and only future returns. One point in the report, viz., that there can be no returns for forty years, clashes considerably with foreign data, since timber of far less age has its commercial value, and, with proper organisation, on the French or German lines, would provide an income in half that time. Let us therefore hope that the Galway catastrophe may at least have a good effect in emphasising the absurdity of its occurrence, and inculcating the need for a salutary preventive system.

MR. JAMES GUTTERIDGE,

Superintendent of Public Parks and Gardens, Liverpool.

Mr. James Gutteridge, whose portrait we have the pleasure of giving in this issue, occupies the important position of Park Superintendent at Liverpool, and is one of the best known and most highly esteemed of the horticulturists occupying public positions in Lancashire, and his popularity is fully justified by his courtesy and commanding ability. Mr. Gutteridge, who is a native of Surrey, commenced his gardening career in the gardens of Burwood House, Cobham, and having gained experience in several other private establishments, he entered on a three years' term of service in the Royal Gardens, Kew. Mr. Gutteridge soon became sub-foreman of the Tropical Propagating Department at Kew, and was so assiduous in his studies that while there he obtained certificates for economic, geographical, and systematic botany, and also for chemistry and physics. He was also successful in obtaining botanical certificates from the Science and Art Department, South Kensington. Leaving Kew, Mr. Gutteridge obtained an appointment in the Glasgow Botanic Gardens, and, after six years' service there, he was appointed curator of the Botanic Gardens and deputy superintendent of the public parks and gardens at Liverpool. During the nine years Mr. Gutteridge filled the dual position at Liverpool he rendered such admirable service that, on the death of Mr. Herbert, the superintendent of the Liverpool public parks and gardens, some three years ago, he was appointed his successor, without the usual formality of inviting candidates.

The "Gardeners' Magazine" Spring Number will be published on the 27th inst.,and as it will be almost wholly devoted to matters that are associated with the season of spring, it will be of special interest to the general body of horticulturists. The contents will include sweet peas and new perpetual carnations; herbaceous phloxes, and pæonies; French beans, and the newer potatoes; amaryllis and gardenias; annuals for the flower garden and conservatory plants from seed; selecting and planting gladioli; the edelweiss; the finest melons and their culture and the future of French gardening. The issue will be profusely illustrated; and, as a large additional circulation is anticipated, we strongly advise those of our readers who require additional copies to give their orders well in advance.

National Horticultural College.—The most important part of the scheme which has been prepared by the Charity Commission under the will of the late Mr. John Innes, of Merton, relates to the institution of a national horticultural college at Merton. This institution will be managed by a council consisting of the three trustees—Mr. C. C. C. Scott, barrister; Mr. F. G. Courthorpe, of Southover, Lewes; and Mr. W. E. R. Innes, of Rossey Park, Horsham—and representatives of Oxford, Cambridge, and London Universities, and other bodies interested in horticulture and agriculture. The institution is established to afford practical and scientific training in horticulture. The grounds attached to Manor Park, Merton, with the exception of two acres used for the horticultural college, are to be appropriated as recreation grounds for the inhabitants of Merton and Malden.

Sir Daniel Morris, K.C.M.G., late Imperial Commissioner of Agriculture for the West Indies, whose portrait we recently had the pleasure of giving in these pages, has been selected for the newly-created office of Scientific Adviser to the Secretary of State for the Colonies on matters relating to tropical agriculture.

R.H.S. Parks Examination.—The report of the Royal Horticultural Society's examination of the employees in public parks, which was held on January 11, has been issued. There were 119 candidates, and of these 25 secured places in the first class, 40 in the second, and 37 in the third, leaving 17 candidates who failed to obtain the minimum marks required. Of those in the first class, about 50 per cent. were in the lower classes last year. The examiners state that the answers to the questions indicated a very fair acquaintance with the practical work of draining, trenching, manuring, soil preparation for planting, and the general cultivation of the soil. In their answers involving thoughtful study, observation, and resource, many candidates showed much weakness. With reference to the classification and naming of trees and shrubs, the examiners report that the majority of the candidates were familiar with the common name of many, but were unable to give their generic or specific names. Their native countries also were but weakly known, and as to those which are distinctly "British," a general haziness of mind existed, the majority of candidates including N. American, Japanese, and New Zealand trees and shrubs as British. The scientific names and the natural habitat of the trees and shrubs of our public gardens would repay a closer study, for nothing interests the public more than to find these points well and correctly set out. An immense improvement is noticed in the understanding of the cultivation of flowering shrubs as compared with two years ago.

Metropolitan Public Gardens.—At the monthly meeting of the Metropolitan Public Gardens Association an intimation was received from the London County Council that West Square enclosure, Southwark, which the association have undertaken to lay out as a public garden, might be enlarged, and it was agreed to incur the additional cost of dealing with the larger area. It was reported that about £250 had so far been received in response to an appeal recently made by Lord Meath, as chairman, for £3,000 from voluntary sources towards the acquisition of Whitton Park, Hounslow, for £11,250. It was decided to prosecute the appeal in various directions. It was reported that the trees granted by the association for Maida Hill West and for Wanstead Flats had been planted. It was decided, subject to estimate, to lay out the churchyard of St. Ann's, Wandsworth, if its maintenance were secured; to protest against the cutting down of trees in St. Martin's-in-the-Fields Churchyard, which had been planted by the association many years ago. It was decided again to organise outside window garden prize competitions in the summer.

Naming of Multigeneric Orchid Hybrids.—The circular letter relating to this importnant question, which we are able to publish in this issue, should have the most careful consideration of all who take an active interest in orchids and orchid culture. Few things could be of greater importance to the orchid cult than the avoidance of long and cumbrous names such as would be formulated by the combination of three or more genera, should the practice in the naming of orchid hybrids continue. We have a strong objection to the practice which has come into vogue within the past few years of coining so-called popular names, but we regard simplicity in the naming of orchids, as of other plants, of primary importance. The adoption of a commemorative name such as that which the sub-committee proposes to submit to the council has much to recommend it. It would be well were those who are interested in the cult of British ferns to meet for the purpose of considering the question of effecting a reform in the nomenclature of the varieties of British species. Possibly it would be better were the council of the Royal Horticultural Society to take the matter in hand.

New Park for Hull.—The Hull City Council has accepted the offer of 30 acres of land for a park and lodges made by Mr. Christopher Pickering. The park is situated in the west of Hull, where the fishing folk live. It was decided that the park should be called Pickering Park.

Experiments with Seed Potatoes. During the past four years several experiments have been carried out, under the auspices of the Education Committee of the Lancashire County Council, for the purpose of obtaining satisfactory information relative between source of seed and weight of crop; and the advantage arriving from the early purchase and sprouting of the seed tubers. The experiments were conducted by Mr. Edward Potter, B.Sc., F.A.C., and R. C. Gaut, B.Sc., and their report, which has just been issued, is at once interesting and instructive. Full details of the experiments and the results are given, and from these the following conclusions have been drawn: Seed potatoes brought from a northern to a southern latitude give a much larger crop than do those brought from a southern to a northern latitude. The yield from Irish-grown seed sprouted, though highly satisfactory, is, on the average, below that from the Scottish grown seed sprouted. Seed potatoes obtained from localities within the county fail on the average to produce crops as large as those obtained from Scottish or Irish grown seed. Seed potatoes obtained early in the year and sprouted before being planted give a larger yield than if obtained late and planted direct (i.e., unsprouted) from bags. The increased yield from seed bought early in the year will repay the extra labour incurred, and at the same time allow of a substantial profit, as, on the average, the crop is increased by more than two tons of large tubers per statute acre by the use of sprouted seed.

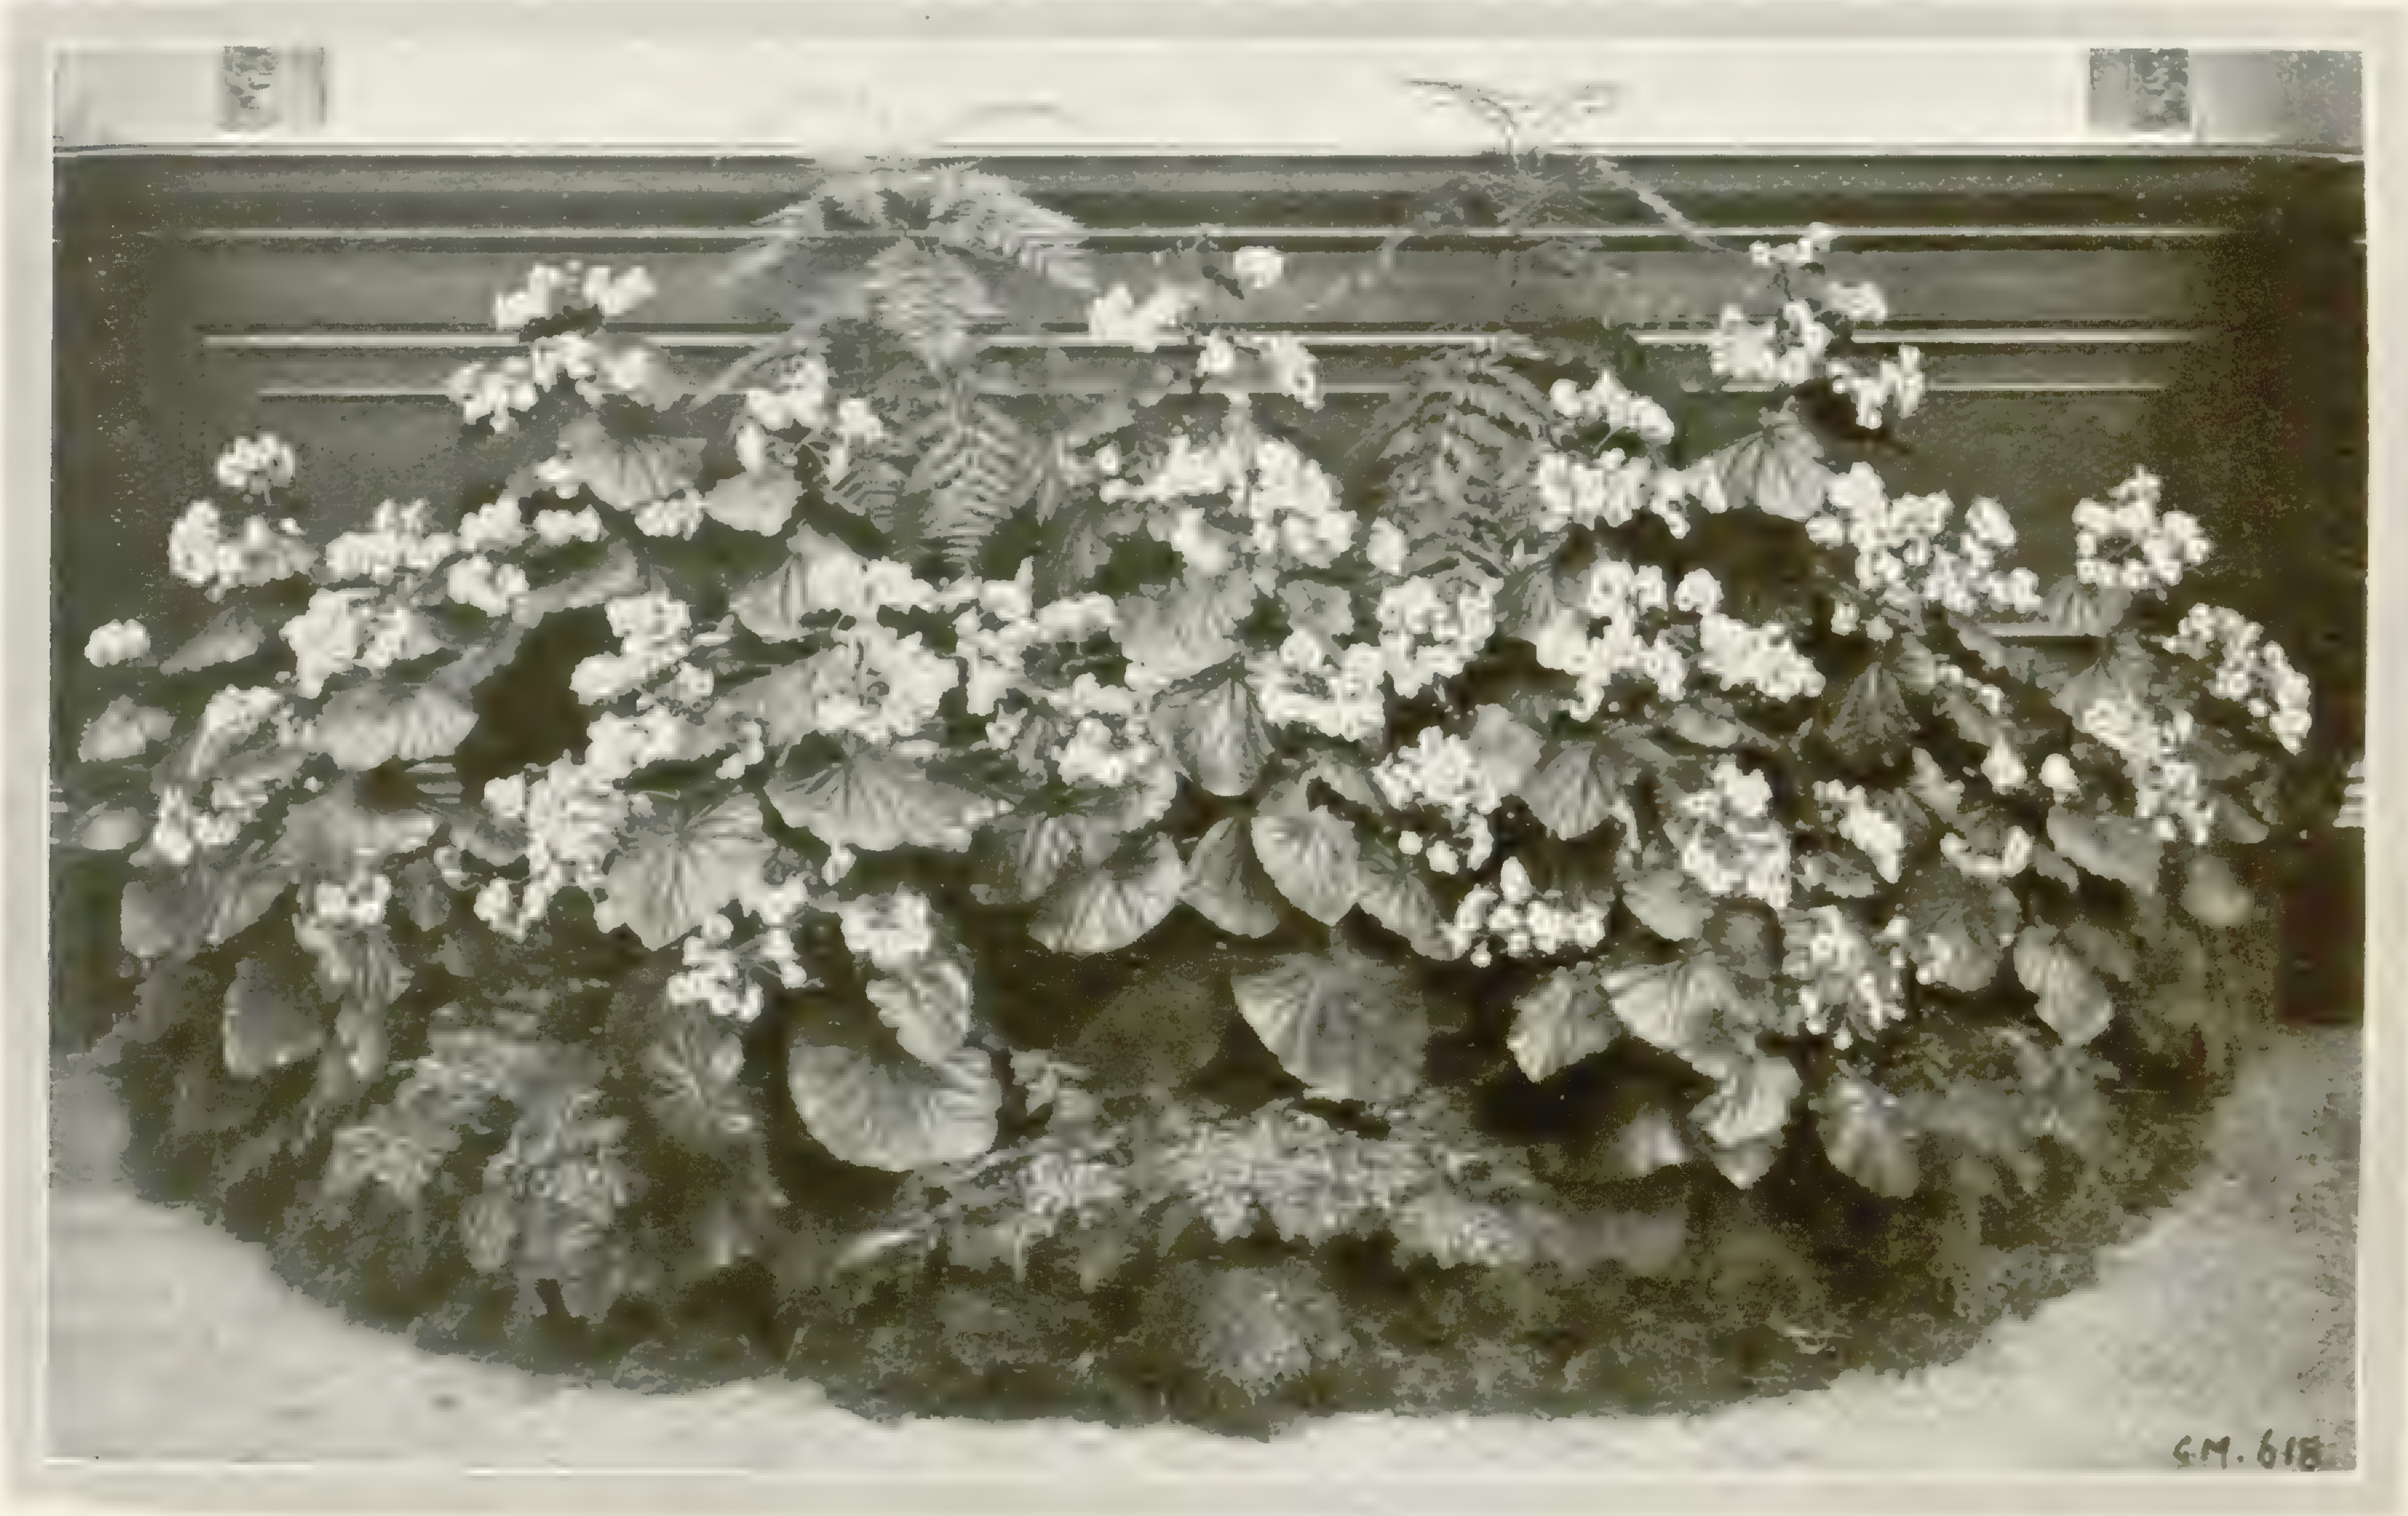
Wisley Trials.—The Council of the Royal Horticultural Society state in their annual report that, in order to protect the members of the various standing committees from the possibility of reproach, and to secure absolute freedom from bias, they have arranged that in future, when trials are being made at the gardens, the growing plants, flowers, or fruits, shall be inspected by a sub-committee composed of five members of the committee interested and that everything so grown for trial shall be kept under a number only, and that the names, both of the varieties and of their senders shall not be disclosed until a decision has been arrived at, and samples are submitted to the whole committee at Vincent Square, together with the report and recommendations of the sub-committee. Thus, the judgments of all sub-committees at Wisley will be given under number only. Specimens of the produce for which a sub-committee shall have recommended any award, will be brought to Vincent Square at the next ensuing meeting, and the whole committee will then have an opportunity of considering the report and recommendations made by the sub-committee at Wisley. The committee having inspected the samples brought up, and adopted (or otherwise) the recommendations of their sub-committee, will send them up to the Council for its approval in the usual way.

Blumea balsamifera is the subject of an interesting contribution to the first volume of the "Indian Forest Record," from Mr. P. Singh. This shrub is of interest as the source of a variety of camphor manufactured by the Chinese, also known as "ngai." While not a competitor with the ordinary camphor of commerce, "ngai" is of considerable value; it is used by the Chinese as a medicine in the preparation of the finer qualities of Chinese ink, and for ritualistic purposes.

BEGONIA GLOIRE DE SCEAUX

To many of those who had an opportunity of visiting the second of the two meetings held by the Royal Horticultural Society during January last, the contributions made by Mr. Prime, the Marquis of Salisbury's skilful gardener, were of special interest. One of these was a bold group of splendidly-grown plants of Euphorbia jacquiniæflora, which, although introduced to cultivation seventy-four years ago, has no equal in its way for decorative purposes during the winter months. Grown with the vigour characteristic of the examples exhibited by Mr. Prime, the plants produce a bright effect in the stove and warm conservatory, and yield sprays of flowers of much value for decorative purposes in a cut state. The other group was of special interest as evidence of the great value of Begonia Gloire de Sceaux for decorative purposes early in the year, when, as in this case, the plants bear the impress of skilful cultivation. The illustration herewith of Mr. Prime's group sufficiently indicates the amplitude of foliage and abundant flower production for which the plants were remarkable, and it will not be difficult to see that such examples of successful cultivation could not fail to be of much value for the embellishment of the conservatory at the present season. It would perhaps be well in some gardens to reduce the cultivation of Begonia Gloire de Lorraine and its several varieties to some extent, and to give increased attention to the variety herewith illustrated, and some of the brilliantly coloured winter-flowering begonias that have been obtained by the intercrossing of Begonia socotrana with the tuberous varieties. Gloire de Sceaux should certainly be more generally grown where the glass space is considerable. This begonia was raised by Messrs. Thibaut and Ketehler, of Sceaux, near Paris, and introduced to cultivation about twenty years ago. The plants have, when allowed sufficient room for their development, a bold pyramidal habit; the leaves are large, and of a rich bronze hue, and the comparatively large bright pink flowers are borne freely, and produce a pleasing contrast to the dark foliage.

G.



A GROUP OF FINELY GROWN PLANTS OF BEGONIA GLOIRE DE SCEAUX.
Exhibited by Mr. Prime, gardener to the Marquess of Salisbury, Hatfield House, at a recent R.H.S. Meeting.

EUPHORBIA JACQUINIÆFLORA.

It is just at this season of the year that we expect to find the most brilliant display of this handsome spurge, and there are few more striking sights than a pillar in a warm house clothed with the rich green of its leaves, from which marvels of colouring the flowering sprays stand out in graceful curves. On walls, when not too closely trained, it often succeeds admirably, but, plenty of light being indispensable, it seldom flowers satisfactorily in such positions should the sun rays be intercepted by climbers on the roof. Although the stove is best suited to its requirements, one often sees it doing well and flowering freely when planted out against the back wall of a light conservatory which is kept moderately warm throughout the winter.

For indoor decoration it would be difficult to speak too highly of the scarlet spurge, which lends itself readily to ornamental grouping. White flowers make the best foil to the intense hue of its blooms, the contrast of colours being pleasing and artistic. A tall vase of paper-white narcissus, with which are interspersed long racemes of the euphorbia, forms one of the most charming floral arrangements imaginable.

The propagation of this euphorbia is best effected by taking off with a heel the young shoots formed by well-ripened plants after the flowering period is over when about four inches in length. Insert them singly in small pots in a compost of peat and rough sand, and place them under bell-glasses. As they are impatient of an excess of moisture, success is rarely attained by an endeavour to strike the cuttings in the propagating frame, where the majority of stove plants are raised. When well rooted their subsequent culture is comparatively simple, as the plants have only to be shifted on when they require it. Good fibrous loam should be added to the potting materials mentioned above, and they should be kept in the lightest position possible. Thus treated they should bloom well during the ensuing winter, and when in flower are useful for conservatory decoration. Some growers plant out in pits, which method induces vigorous growth and a plentiful supply of sprays for cutting; but, naturally, such treatment fails to display the beauty of the growing plant to the best advantage. On no account should the soil in the pots or beds be allowed to become saturated with water, such conditions being fatal to health. When the pots or beds are well filled with roots, liquid manure should be supplied to maintain the fertility of the soil.

T. B. Field.

Ashwellthorpe Gardens.

Strawberries in Flower should be allowed a good circulation of warm air, as a close atmosphere is not at all conducive to a good set. In the middle of the day, when the pollen is quite ripe and dry, it should be scattered by means of a fan or brush. Take great care the plants do not become too wet at this stage. As soon as it is seen that a crop has set the fruits should be thinned, for at this early season heavy cropping would mean failure. Top dress the soil with some approved manure.—W. A. Cook.

SOME NEW ROSES OF 1907—I.

◆

FIRST IMPRESSIONS.

The following notes on new roses of 1907 are just first impressions; nothing more. You could not expect more from an amateur than first impressions, could you? From a desire to increase the stock of plants many new roses are over-propagated; the plants are weak to start with, and they will probably take a year or two to recover themselves. But because a certain novelty is degenerate the first year of its introduction, that is no reason why it will remain so. Time after time there have been instances of a new rose which at first was apparently weak and almost worthless, becoming, as time went on, a first-rate variety. Some of these first impressions are more decided than others, since the roses criticised in the subjoined list fall under three heads. Division (1), those that the writer has himself grown and tested; (2) those seen growing elsewhere, and (3) those seen only at exhibitions, and it is obvious that he is in a slightly better position to judge of the roses in Division 1 than of those in Divisions 2 and 3.

SWEET PEA MRS. HENRY BELL.
Flowers large, colour cream, richly suffused with bright rose-pink.

Division I.

Ami Martin, H.P. (Chedane).—Colour vermilion red, deep petals, but so far lacking in form and substance.

Avoca, H.T. (Alex. Dickson and Sons).—Colour dark crimson flushed with scarlet. On maiden plants the flowers are produced at the tips of very long medium-sized wood. Of good form and deep petalled, but lacking in fullness. A late flowering variety. At present the colour and lateness in flowering are its only recommendation. It may be better as a cut-back.

Barbarossa, H.P. (Welter).—Colour carmine-red, vigorous and free flowering. A large flower, but at present too thin and irregular in outline to be useful. The raiser terms it a red Frau Karl Druschki! It may be so on the Continent, but up to the present I cannot endorse this description.

Birdie Blye, Hybrid multiflora (Conard and Jones).—Colour carmine-pink, but the pink lacks yellow, whereby it loses in brilliancy. Flowers small, produced in clusters blooming at the terminals. Vigorous branching habit. Will make a good bush, but is not a pillar rose. Perpetual, good autumnal. The weakness of this variety lies in the deadness of the colour.

Colonel S. R. Williamson, H.T. (Alex. Dickson and Sons).—Colour white, with blush centre, deep petalled, pointed, full. Very free flowering, useful for decoration, and giving good exhibition blooms early in the season.

Dorothy Page Roberts, H.T. (Alex. Dickson and Sons).—A semi-single rose, pink suffused yellow. Flowers of long, stout petals, produced singly, pairs or triplets, but not more. It was awarded the gold medal of the N.R.S., but from personal acquaintance of maiden plants the award seems hardly justified. It may be better as a cut-back; its habit, however, is not sufficiently branching for garden effect.

Elizabeth Barnes, H.T. (Alex. Dickson and Sons).—In colour this rose resembles Madame Abel Chatenay. It is irregular in form and wanting in size, substance, and depth of petal.

Harry Kirk, Tea (Alex. Dickson and Sons).—Colour, buds apricot yellow, shading paler in the more advanced flowers. Robust, branching habit, deep green foliage, apparently not liable to mildew. Producing abundance of flowers on thick upright stems, flowering continuously well into the autumn. Blooms of sufficient size and quality as an exhibition tea. An excellent garden variety. One of the best. Gold medal, N.R.S.

Lady Helen Vincent, H.T., (Alex. Dickson and Sons).—Colour shell-pink. Commended by the raisers as giving blooms large, full, pointed, of good form, and fragrant. It was awarded the gold medal of the N.R.S. It has not, however, at present reached one's expectation.

Mrs. Harold Brocklebank, H.T. (Alex. Dickson and Sons).—Colour cream-white, base of petals buff-yellow. Of good form, but too thin and lacking in size for exhibition purposes. As a garden decorative variety it may possibly be found more or less useful.

Marichu Zayas, H.T. (Soupert et Notting).—Colour rose-pink. Flowers large, deep petalled. Vigorous upright growth. But so far, it has been deficient in form and substance.

Mrs. J. W. Budde, H.T., (Soupert et Notting). — Colour bright carmine. Flowers of good size, but wanting in fulness. Before expressing a decided opinion on this and the last-named variety one must test them another season. At present I do not care for either.

Queen of Spain, H.T. (Bide and Son).—Colour pale flesh. Grand flowers have been staged by the raisers, very full and of good form. My experience of it is on cut-backs only, when the growth was weak and the flowers worthless. Possibly a result of over-propagation. Perhaps on maidens it will give better flowers, but I should think it is solely an exhibitor's rose. Awarded the gold medal of the N.R.S.

W. E. Lippiatt, H.T. (Alex. Dickson and Sons).—Colour velvety crimson, shaded maroon, very strongly perfumed. Flowers large, good form, pointed, and very full. Petals stiff and leathery. In the blossoms of this rose there is a suggestion of Earl Dufferin in its best form, but the growth is stronger and more upright. The foliage is very handsome. Here we have a most promising rose and one that will probably be extremely useful to exhibitors, especially in a hot season. It is a welcome contrast to the many flimsy varieties of recent introduction.

Joseph H. Pemberton.

Small Holdings.—We understand that a short amending Act will be introduced next Session dealing with the interpretation of the word "holding," and defining it to be the amount of land farmed, and not the particular size of any piece of land. As the Act stands at present, only members of the labouring population can secure allotments, but it is felt that it should be made permissible for allotment authorities to provide allotments up to five acres to all suitable persons.

THE BEST SWEET PEAS.

Those who would achieve success in the cultivation of sweet peas during the coming season must, within a comparatively short period, if they have not already done so, be on the alert, and take the preliminary steps essential to the production of an abundant and beautiful display of flowers. In other words, they must select the varieties they intend growing, purchase the seeds, and proceed with sowing them under glass, or in the open, as may appear the most desirable. The first step is to make a selection of varieties, and to those who have not had an opportunity of becoming acquainted with the newer introductions this is not wholly free from difficulty. This, however, is much less difficult than it might have been, for the National Sweet Pea Society has, by means of its trials, been able to thoroughly test novelties, classify varieties that are too much alike, and to eliminate those of inferior merit. The growers and raisers have heartily co-operated with the society in its excellent work, and, as the result, a selection might be made from any good catalogue without the risk of including a variety that is decidedly inferior. There are, of course, different degrees of merit, and because of this the following selection has been prepared for the guidance of those who require a comparatively small number of varieties.

In the making of a selection of sweet peas there is no occasion to place a severe limit upon the number of varieties, as in the case of many ornamental plants and useful crops. The amateur may, if he so chooses, have as many distinct varieties as he has clumps, for the varieties differ but little in growth, and there is no danger of any two colours being so wanting in harmony as to produce a really unsatisfactory effect. Sometimes the question of cost arises when the purchase of a comprehensive collection is contemplated, but the seeds of sweet peas are so inexpensive that those who require a medium-sized collection have no occasion to consider the cost. The cultivator has only to turn to the advertisement pages of the **Gardeners' Magazine** to find that he can obtain a collection of twenty varieties or so of great excellence for five shillings, which is not a large sum for the production in the garden of a display of flowers equally remarkable for their attractiveness and fragrance. In gardens where large quantities of flowers are required for decorative purposes in a cut state it will be necessary to reduce the number of varieties somewhat, and increase the area for those bearing flowers of the colours for which there is the greatest preference.

Where there is room for a representative collection, three of the four varieties that obtained distinction from the National Sweet Pea Society last year should be included. All the varieties are of much merit, but the brilliant crimson George Stark will not be distributed until next year, and cultivators must therefore possess themselves in patience. The others are Mrs. A. Ireland, of which an excellent illustration was given in last year's volume of the **Gardeners' Magazine**, an attractive variety, similar in colouring to Jeannie Gordon, but with larger blooms, and a finely waved standard. Mrs. Henry Bell is exquisitely beautiful; the flowers are large, of great substance, and exquisitely coloured, the ground being rich cream suffused at the margin of the petals with rose-pink. Constance Oliver, a charming variety, has flowers large in size, with finely waved standard, the colour deep pink suffused with cream at the base of the petals. Paradise Ivory has large, finely formed flowers, with stout waved petals, and of a pleasing ivory colour.

SWEET PEA, EVELYN HEMUS.
Flowers large, colour rich cream, suffused with rose-red at the margin of the petals.

In passing on to other varieties, of which the majority have been some time in cultivation, one finds so many deserving attention as to experience some difficulty in certain sections in determining which to leave unnoticed. In the group of white varieties there are three of outstanding merit, and these are Etta Dyke, Dorothy Eckford, and Nora Unwin. The first and third belong to the waved section, and the second has plain standards, and where two only are required the first and second should be selected.

The various shades of pink are sufficiently numerous to afford a considerable range for selection. Mrs. Hardcastle Sykes may be mentioned as one of the finest of the varieties with blush-coloured flowers, and as deserving of the most widely extended culture. There are several others so closely akin to Mrs. Hardcastle Sykes that they have been bracketed by the National Sweet Pea Society as being "too much alike," a fact of which growers for exhibition should make note. Countess Spencer still remains at the head of the deep pink varieties, and, with Constance Oliver, of which mention has already been made, will be sufficient. Of the rose and carmine shades, John Ingman should be selected; the flowers are large, and the standard elegantly waved, and the colour is brilliant carmine-rose.

There are several excellent varieties with flowers of various shades of yellow, and of these James Grieve, a variety with large, stout sulphur-yellow flowers, can be specially recommended. One does not like to leave Mrs. Collier unnoticed, but James Grieve and Paradise Ivory will be enough yellow forms for a collection of considerable extent.

The scarlet and crimson sweet peas have been considerably strengthened within the past few years, and the finest of these are of special value both for the production of colour effects in the flower garden and the supply of cut flowers for indoor decorations. It is highly satisfactory that the two varieties of exceptional excellence should have received names in every way worthy of their merit, by having been dedicated to King Edward VII. and Queen Alexandra. They have both a strong constitution, are free in flowering, and the blooms are of the largest size and good substance. The flowers of King Edward VII. are glowing crimson, and those of Queen Alexandra rich scarlet. Chrissie Unwin is a beautiful variety, bearing large flowers with waved standards, and of a lovely cerise shade. Helen Lewis and St. George are two highly effective varieties belonging to the orange-coloured section, and should have attention.

Varieties with flowers of various shades of blue and mauve form an important group, several of quite exceptional excellence having been introduced to cultivation within the past few years. Of the deep blue shades Lord Nelson, similar in hue to Navy Blue, but brighter in colour, and in other respects superior to it, and A. J. Cook, a large flower with waved standard, and of a pleasing shade of purple-blue, should have the preference. Lady Grisel Hamilton is still the finest of the lavender-coloured sweet peas, and with it should be associated Frank Dolby, a charming pale blue variety, with waved standards. Rosie Adams has purple-mauve flowers, finely waved, and is of much merit, and Mrs. W. Wright and The Marquis are mauve-coloured varieties of much merit, the last-named having waved standards. Menie Christie and George Gordon are the finest of the magenta coloured varieties, and are very beautiful when seen at their best, but in dry seasons and on shallow soils the flowers lose somewhat of their lustrous colouring. The first has waved standards, while of the second the standard is plain. Still darker in colour are Black Knight and Hannah Dale, which have deep maroon flowers, with plain standards.

Very beautiful is Evelyn Hemus, a distinct variety, with large flowers, having waved standards, the ground colour rich cream, with a well-defined rose-pink margin to the petals. Sybil Eckford is a distinct fancy flower, exquisitely coloured lemon, apricot, and blush-pink. Jeannie Gordon, although introduced eight or nine years ago, is still the best of the bicolors, and of much value both for exhibition and garden decoration. The flaked varieties include several that should be grown where the space can be afforded for a comparatively large selection. Prince Olaf is the best of these with blue markings, and Jessie Cuthbertson and Paradise Red-flake are the finest of those in which the colouring is rose and red. Helen Pierce continues the best of the marbled section. Marbled flowers are useful for exhibition because of the distinctive colouring they afford, but as compared with the selfs they are somewhat wanting in effectiveness in the garden.

The varieties enumerated include the finest in the respective shades of colour, and are essential to a representative collection. Should, however, the number be in excess of the requirements of those who refer to the selection, the varieties representing colours that are not specially appreciated should be omitted, and one only of each of the other shades of colours be selected, preference being given to the first mentioned of each shade. S.

The Potato Supply.—Last autumn we were congratulating ourselves on the excellence of potato crops, and, according to official returns, the crop was about one ton to the acre more than in 1907. Perhaps the absence of disease in the tops during the summer, and the fact that the tubers grew unchecked, were responsible for the heavy crops, but now we are hearing the other side of the story—people cannot sell their potatoes. One is inclined to wonder, after all, whether big crops are really a blessing, for the indispensable tuber is now going begging, and the average price is little more than half what it was a year ago. Whether the trade will improve later on remains to be seen, but at the moment farmers are freely using potatoes as food for cattle, not for choice, but because they consider this to be a more economical way of disposing of them than selling at the prices offered. The slump in the potato trade will probably result in a less area being planted next season, as growers will fear running a second risk of over supply.—H.

Fuchsias that have been stored away in a dry shed or some other such place should now be brought out and put in a house where a temperature of about 50 deg. is maintained. A few days subsequently they should be pruned hard back, and in most cases close to the old stem, as they break much better from really old, hard wood than from that which may not be fully matured. Syringe them daily, and when the young shoots have attained the length of one inch they should be repotted, removing a good portion of the old soil, also shortening in the stronger of the roots. Young plants struck in the autumn and now in three-inch pots should be ready for a shift into others one size larger, using a nice light compost. It is advisable to pot fairly firm, which will tend to keep the growth sturdy. If bushy plants are needed to bloom in small pots, once pinching of the main shoot will suffice, but if good pyramidal specimens are needed to bloom later on in the season the main shoot must be encouraged, and as the side shoots develop they must be pinched at the second pair of leaves.—Thomas Stevenson.

NOTES FROM KEW.

When a greenhouse has to be kept gay with flowering plants throughout the year, many of our hardy shrubs brought on under glass so that they anticipate their usual season of blooming are exceedingly valuable for the purpose. This is at the present time well exemplified in No. 4 greenhouse at Kew, which is very instructive and delightfully attractive at all seasons, but owes a good deal of its beauty just now to the numerous examples of forced shrubs which are plentifully scattered throughout the structure.

Rosaceous plants are, as one might expect, strongly represented, there being among others a tall specimen of the purple leaved variety of the cherry plum, well known in gardens as Prunus Pissardi, but whose true name, according to the Kew authorities, is Prunus cerasifera atropurpurea. In its flowering stage the leaves are not developed, but the pretty white blossoms, slightly tinged in the centre, when borne in such profusion as in the Kew specimen, are most attractive.

Other species of prunus in which genus are now included the cherries, almonds, and peaches, as well as the plums, are Prunus pseudo cerasus, a beautiful semi-double Japanese cherry, the flowering season of which is, in its native land, made the occasion of an annual fête; Prunus sinensis, a neat-growing little shrub, whose comparatively long slender shoots are thickly clothed with pretty double blossoms, pure white in one variety, and slightly tinged with pink in the other; Prunus triloba, with semi-double flowers of a pleasing shade of deep pink. Apart from its value for forcing, this prunus, which, by the way, is sometimes known as Amygdalopsis Lindleyi, is a delightful wall shrub. Grown in this way the flowers are much richer in colour than they are under glass. The last of the prunus to mention is that richly coloured member of the peach family known as Prunus persica magnifica. The deep reddish rose coloured blossoms of this afford a pleasing variety to the lighter tints of the others.

Spiræa arguta, represented by some large bushes thickly studded with their clusters of tiny white flowers, is as attractive in the greenhouse as it will be later on out of doors. Spiræa prunifolia flore-plena, remarkable among spiræas for its double blossoms, lends itself to forcing as readily as the preceding. The dark coloured bark of the branches serves to intensify the spotless purity of the little rosette-like blossoms. The June Berry of North America, Amelanchier canadensis, is seldom forced, but its white flowers are freely borne when treated in this way.

Finally, among rosaceous plants there is Pyrus floribunda, whose spreading branches are thickly wreathed with pinkish blossoms. When forced, these are much paler in colour than when they develop out of doors under the influence of spring sunshine. Azalea sinensis, more generally known as A. mollis, is represented by various forms, differing principally in their shades of colour. They are, however, all of a yellowish or terra-cotta tint. From the readiness with which it can be forced, this azalea is largely grown for the purpose.

Rhododendron præcox, that valuable hybrid between the Himalayan R. ciliatum and the little purple-flowered R. dahuricum, is very attractive when in full flower. A second variety, Rosa Mundi, with light-coloured blossoms, is a compact grower of the caucasicum type, and, as seen at Kew, is particularly adapted for flowering in pots early in the year.

Lilacs in the shape of good sized bushes are full of flower, while especially noticeable is a group of the pure white variety, Marie Legraye, grown in quite small pots, yet each is carrying several clusters of blossoms.

There is also a group of dwarf plants of the guelder rose, Viburnum opulus sterile, and some good examples of Staphylea colchica, whose fragrant flowers are much more attractive in the greenhouse than they are out of doors. The last to mention is Jasminum primulinum, which in the open ground is not always the success that was at first anticipated, but under glass early in the year it is delightful, the long, arching shoots being wreathed for a considerable distance with golden blossoms. K.

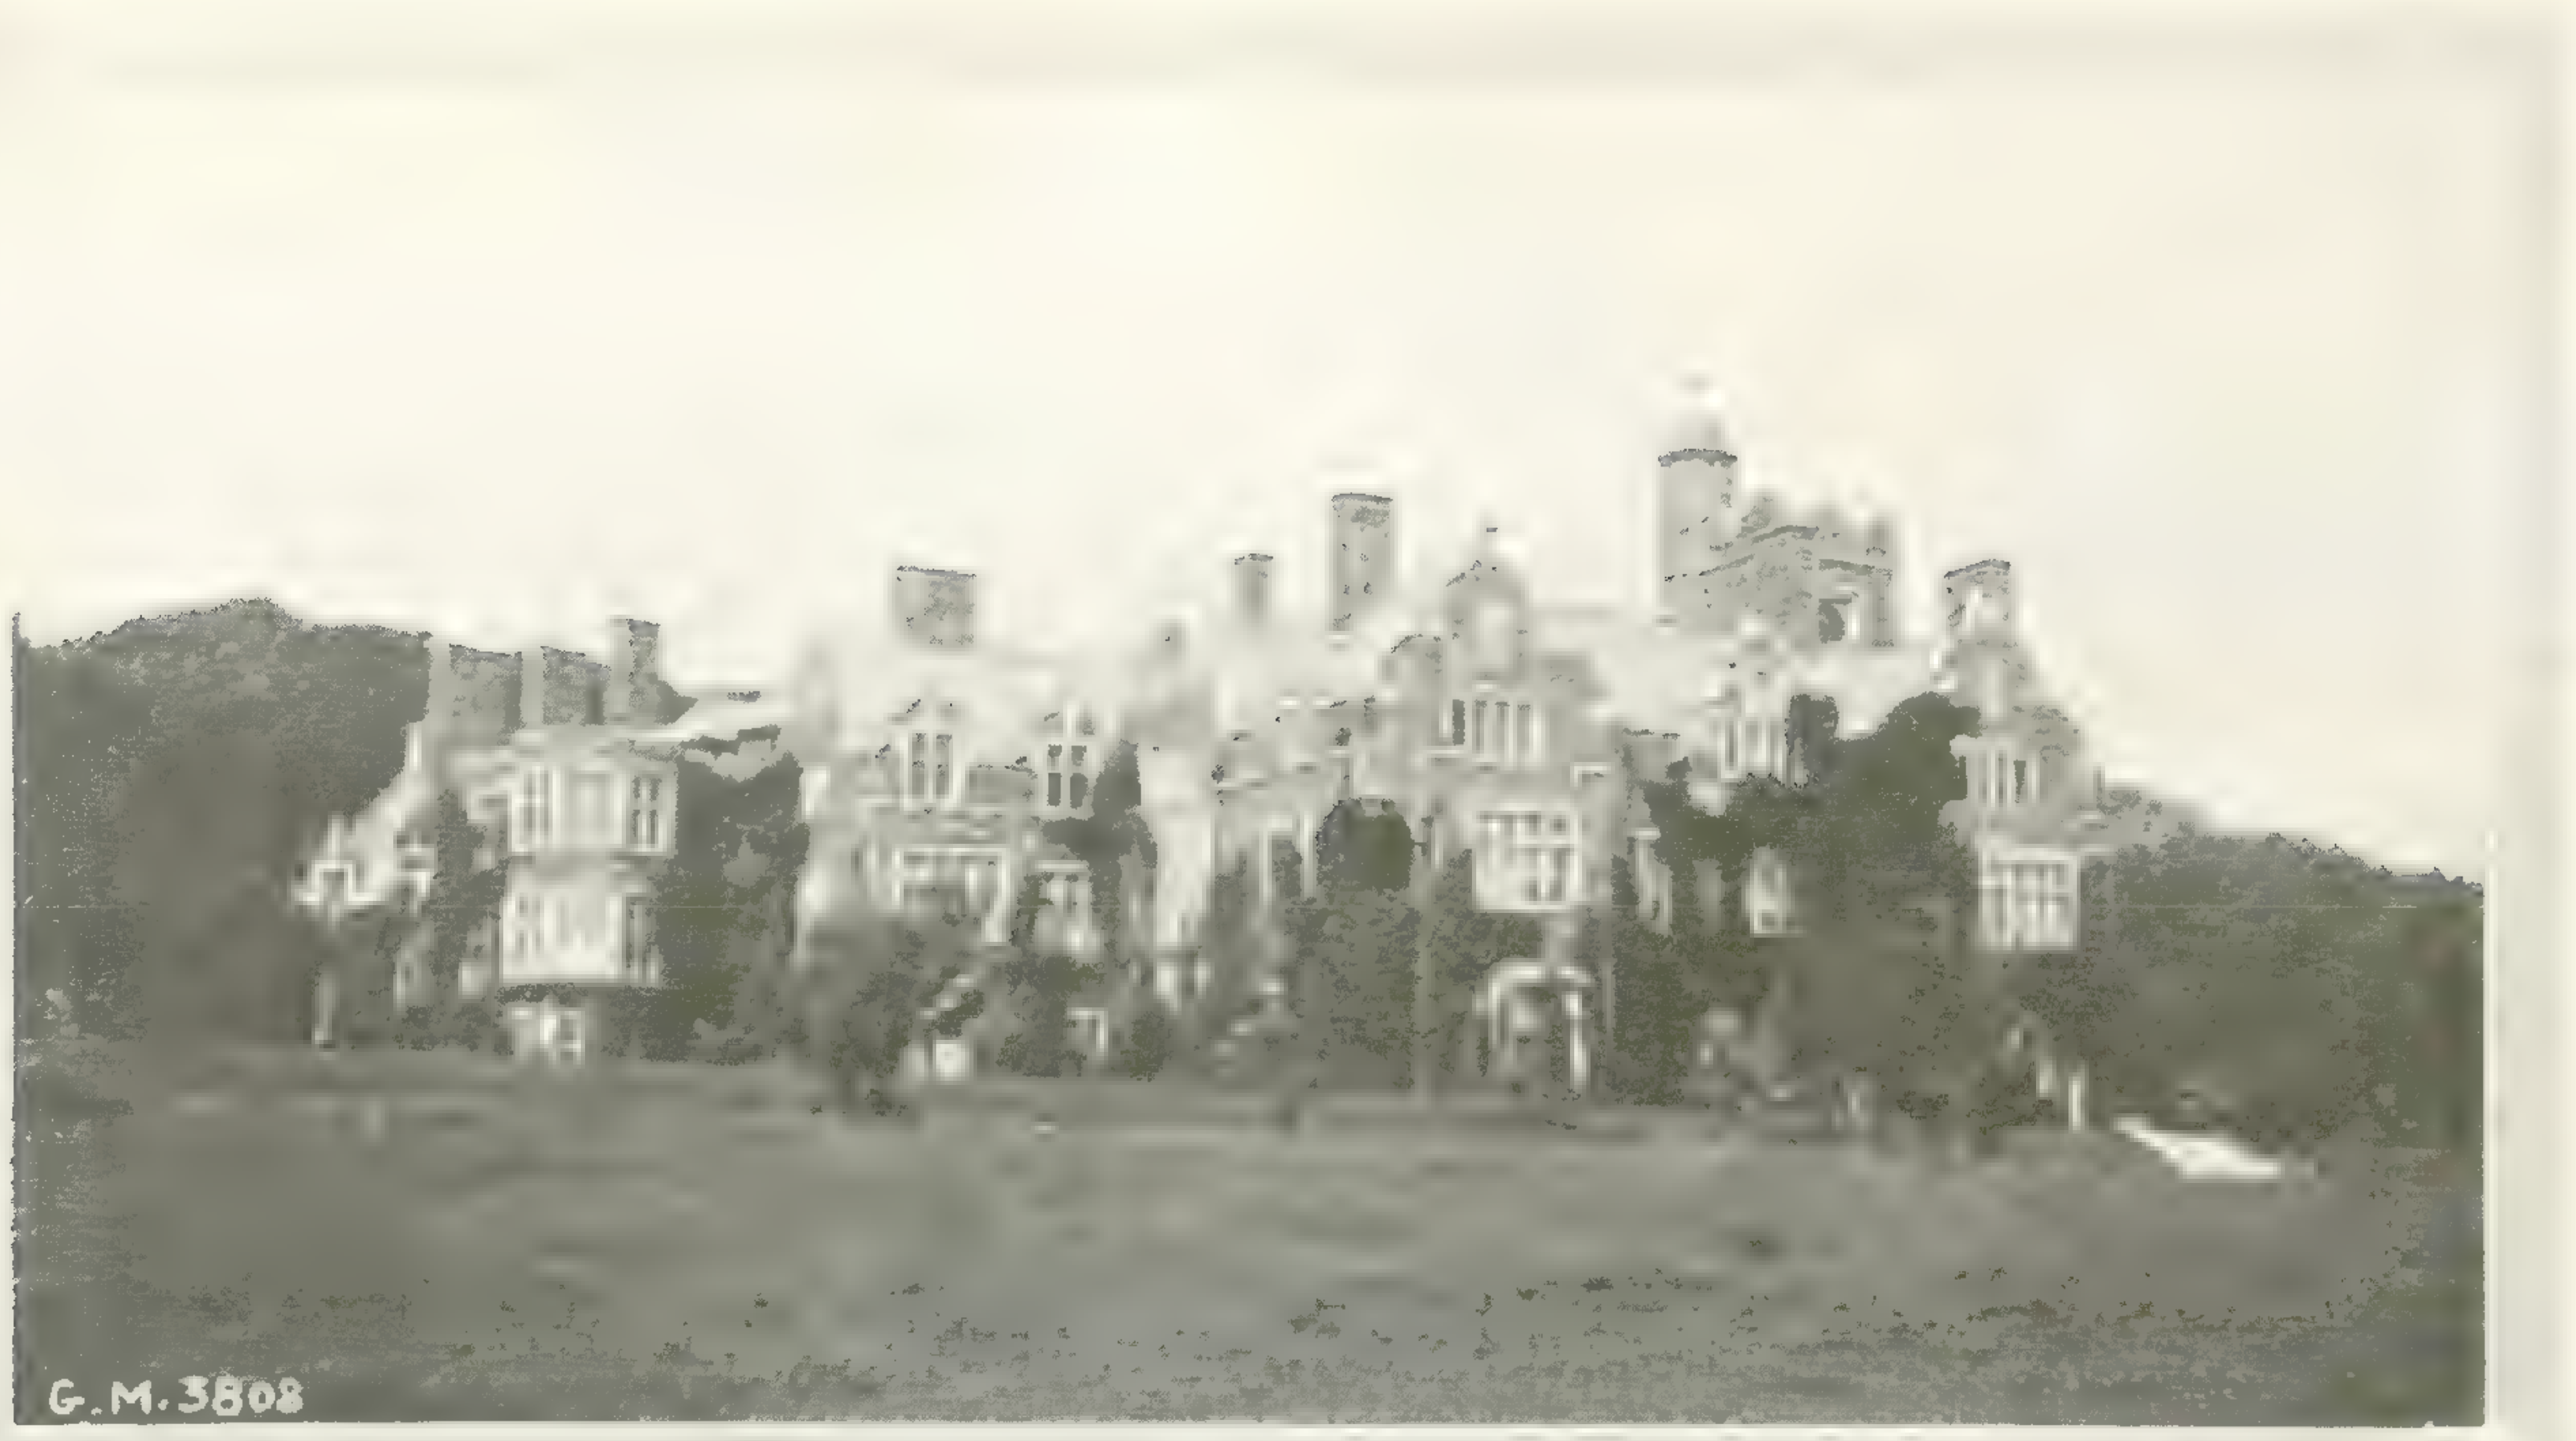
RED OR GRIZZLY GRAPES.

A mere glance at the article on this subject (p. 93) is sufficient to prove to me that "Grizzly Frontignan" is much behind the times in his ideas, or he would know that the rage for big grapes has long since passed away, whereas he would have us believe the rage for such examples is but coming! I am not an advocate of big bunches by any means, but I endeavour to produce good-sized bunches, with large berries for the variety, and decidedly good colour, and, what is of more importance, extra good flavour. In such specimens as these we have all the attributes of a perfect grape, and, therefore, it is not necessary for any gardener to grow red or grizzly coloured sorts, except it is that he wishes to hide his inability to colour perfectly such like Muscat of Alexandria or Madresfield Court, which are admittedly two of the finest grapes in existence. When we have varieties like these, that will give heavier crops, of much better flavour, and lasting over a much longer season than any red or grizzly variety that can be named by any correspondent, I would ask where is the sense of growing such sorts as advocated by Mr. Curtis or "Grizzly Frontignan."

I have had so much to do with the supply of a private table that I know extra-large bunches are not economical, apparently. ["Grizzly Frontignan" has supplied a larger table, and over a much longer period, than Mr. Molyneux.—Ed. G.M.] "Grizzly Frontignan" has not (quite likely not) had such experience. Your correspondent should know that Worcester Pearmain is the most popular apple in September, from any point of view, therefore his reference to it is of little value in his effort to push these grizzly grapes, of which he cannot point to a living example in one hundred cases where grapes are grown at all, and this is the best test of the value of anything, for if any subject is difficult to find (outside of a botanical garden) then there is precious little strength in the argument for its use. I respect "Thompson's Book on the Vine," but what happened in the day when this was written does not apply to present-day practice or requirement.

It is many years ago since Duchess of Buccleuch won the premier award for flavour in Edinburgh. Madresfield Court has won the prize many more times since. How many vineries can "Grizzly Frontignan" point to where Duchess of Buccleuch is grown at all, and how many Grizzly Frontignans can he refer to as now existing? Can he point to a vinery which does not contain a Madresfield Court or Muscat of Alexandria? It is not news to learn that the small, highly-coloured Muscat berries referred to are of high flavour, but what grape grower aims at getting these small, stoneless berries purely because they are of high flavour? It is too absurd. E. Molyneux.

GRAPES AND HOW TO GROW THEM.—An illustrated guide to propagation, culture, and management in vineries, greenhouses, and in the open air. By J. Landell, F.R.H.S. Price 1s. net, by post 1s. cloth, 1s. 6d., by post 1s. 8d., from W. H. and Collingridge, 148 and 149, Aldersgate Street, London.



BOSAHAN: THE GARDEN FRONT.

SOME MORE CORNISH GARDENS—II.

Bosahan.

Bosahan the beautiful, on the south bank of the broad and delightful estuary of the Helford River, lies quite away from the route of the pedestrian tourist, and as it is about seven miles from the nearest railway station, it is not frequently visited by horticultural scribes. The estate is a large one, and as it runs along the bank of the Helford for a considerable distance, some wonderfully fine views both up the river, out towards the sea, and of the wooded cliffs across the way, are to be obtained from it.

The road to Bosahan runs almost due south from Falmouth to the Helford Passage, where one has to take the ferry. As Mr. J. Rundle was expecting me I was able to land at the private landing place and walk up through the well-wooded grounds to the fine mansion that is the home of Colonel Sir Arthur Vivian, K.C.B. It has been my good fortune to visit a very large number of private gardens throughout Great Britain and Ireland, but I do not remember one so exceptionally distinct from all others as this one of Bosahan. There is a certain type of garden to which a great number of Cornish gardens conform more or less, and, broadly speaking, it consists of setting the house at the head of a valley that gradually opens out towards the sea or river. The planting consists of wonderful rhododendrons, rare conifers, acacias, etc., and water and bog gardening are conducted as a matter of course in connection with the water that runs through this valley. It is all very beautiful, and also very wonderful, especially to those unacquainted with the climate of Cornwall, but there is, after all, something of monotony in the ever recurring Himalayan rhododendrons.

Bosahan is the most Cornish of all Cornish gardens, and yet it is very distinct and striking. It has its complement of choice rhododendrons, azaleas, etc., but its fame will, I think, rest upon its palm and tree fern groves than upon anything else. The garden has been carried out little by little into a long sheltered woodland valley that presently ends at a low cliff overlooking one of the Helford creeks. Little walks run right through this Valley of Palms, winding amid the trees, and round the rhododendrons, passing great breadths of hardy ferns, including Osmunda regalis, and coming now and again upon small clearings, where groves of Dicksonia antarctica or Trachycarpus excelsa have been planted. All along the valley one notices the trachycarpus is planted wherever there is a suitable opening, so that in years to come they will be the dominant feature of the valley. There are well over two thousand of these palms at Bosahan, and not one of them receive protection in winter. The work of planting has been steadily carried on for about twenty-five years, and I should like to visit Bosahan twenty-five years hence, by which time a large number of the plants will have reached a fair size.

Wherever the valley gives a sudden dip the tree ferns have been planted, so that now and again you come suddenly to the end of a rising path, and look out over a group that may contain from fifteen to fifty tree ferns, and that suggests Australia or New Zealand, and you instinctively peer under the spreading dicksonia fronds for a kangaroo or an emu, or you rub your eyes and wonder whether you really are still in England. But the millions of daffodils in the valley and the acres of bluebells and primroses are more homely and not less beautiful, though less striking than the ferns and palms.

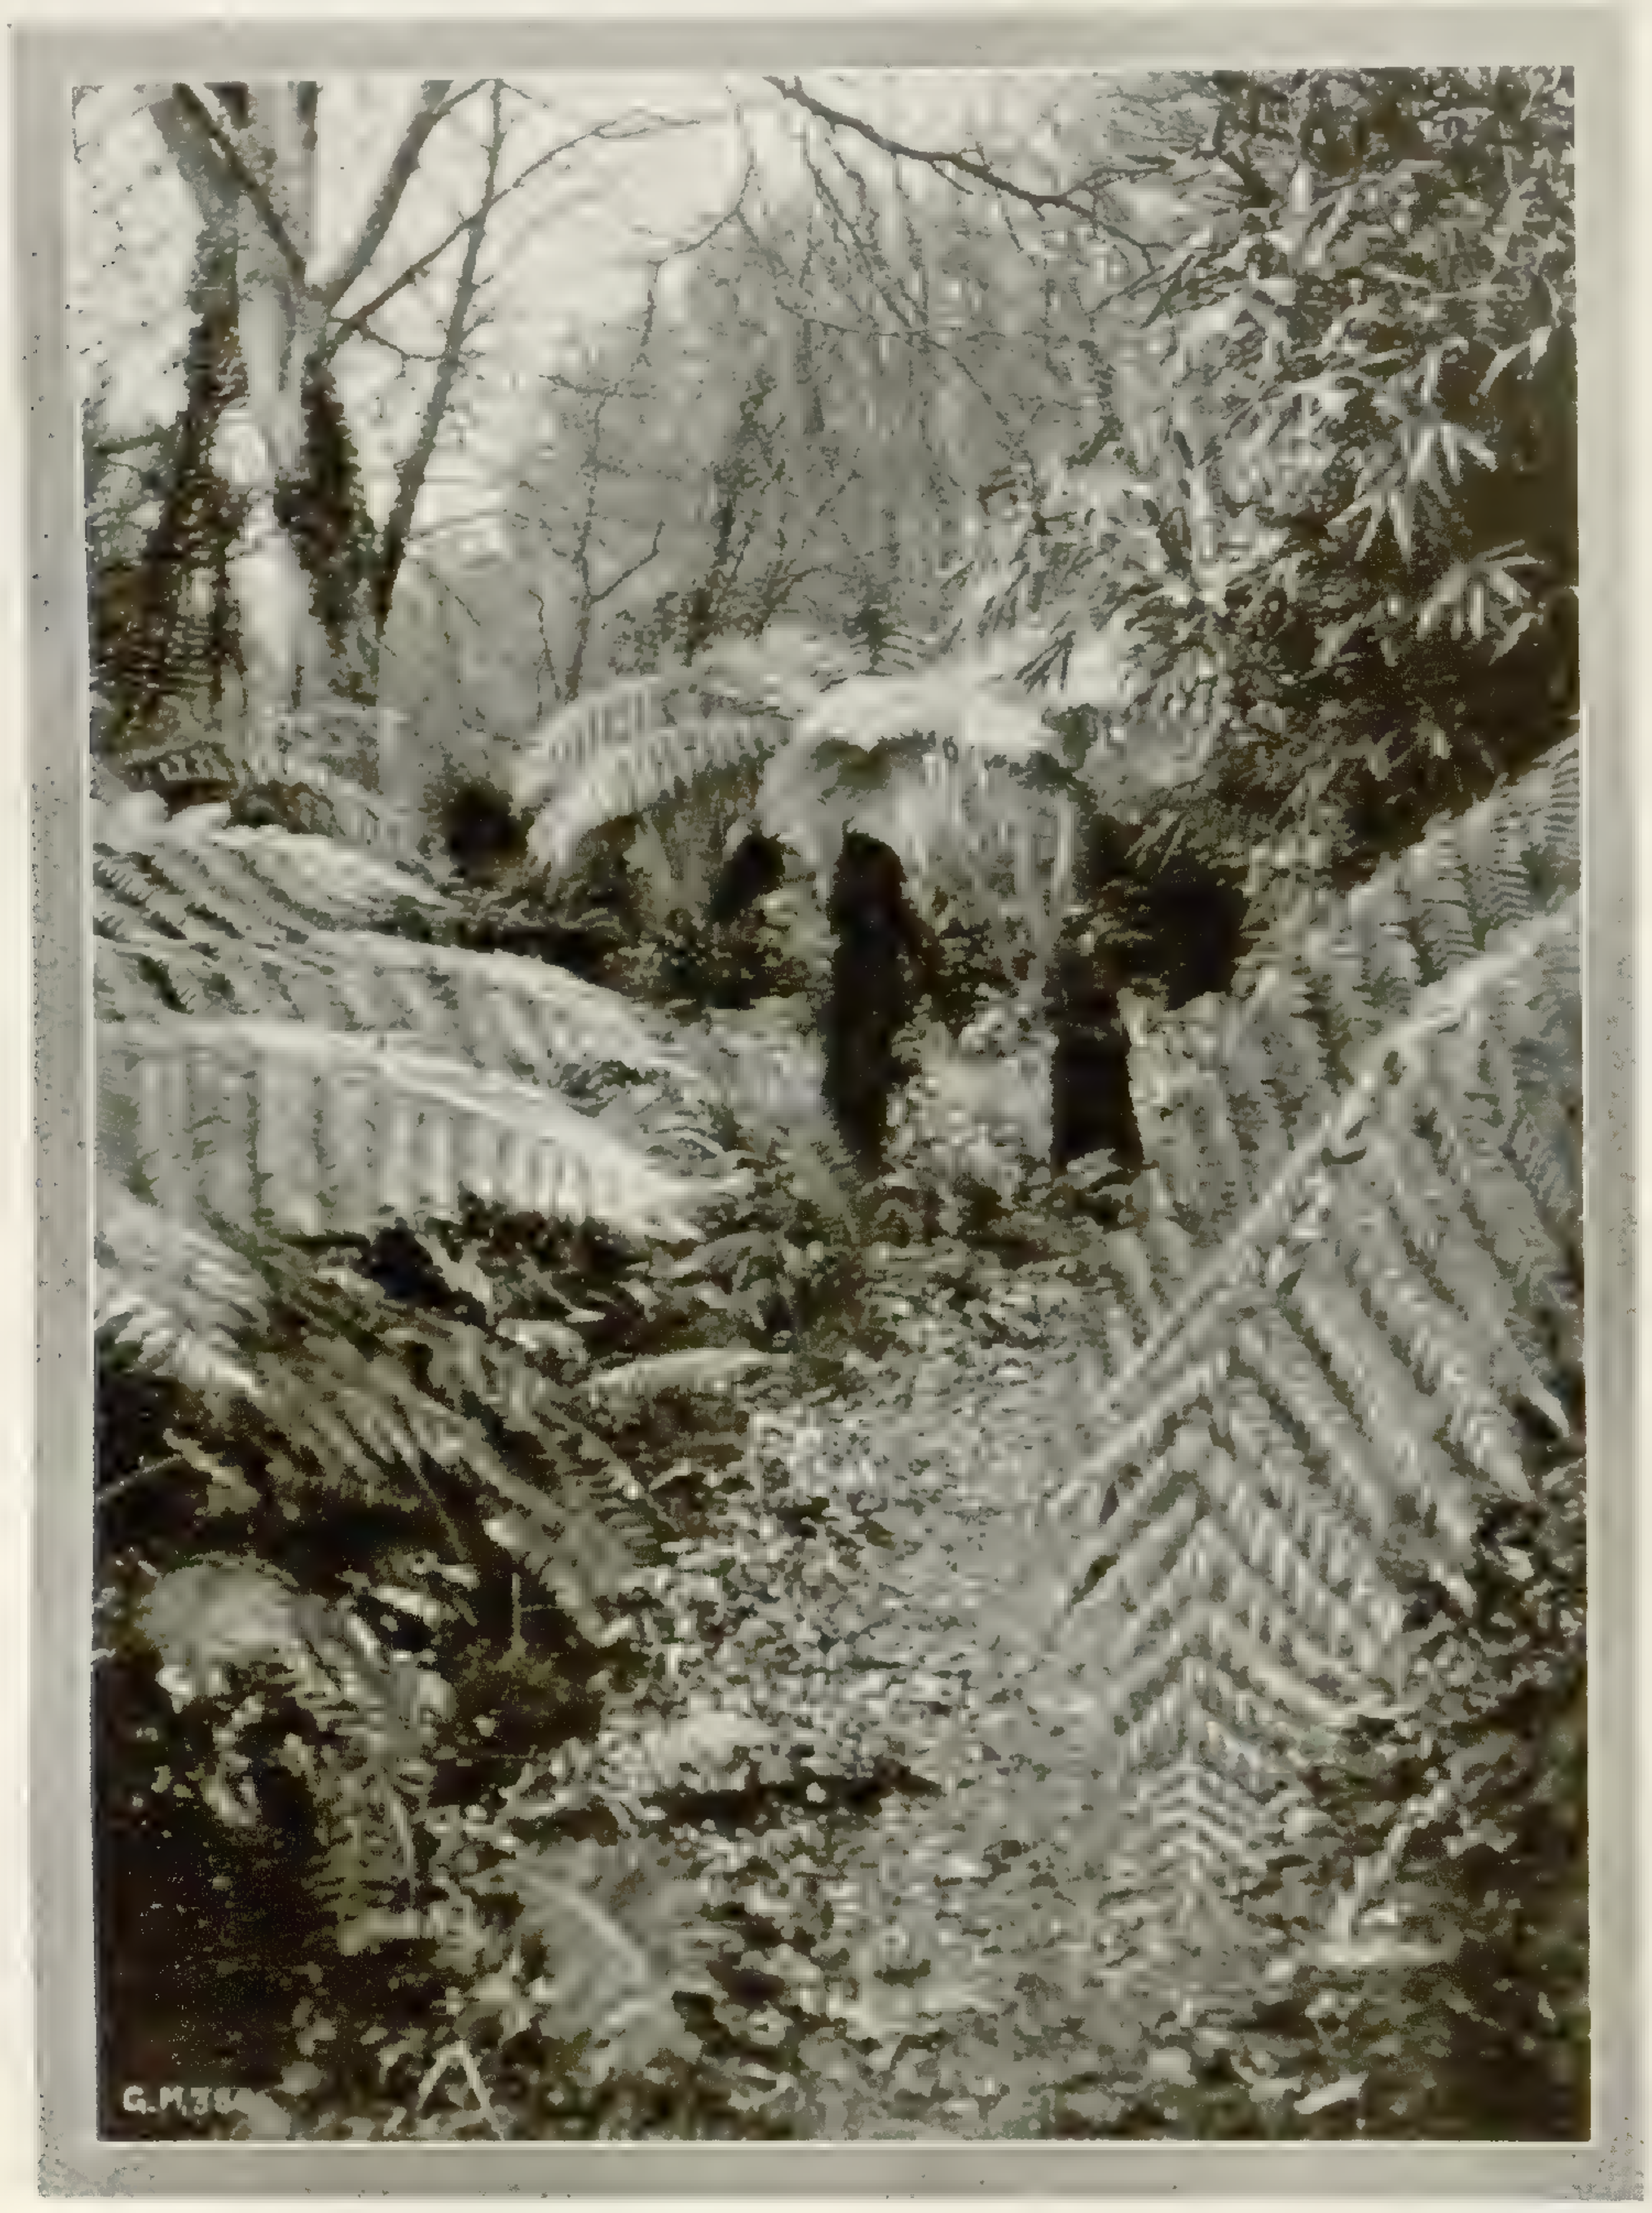
If I have wandered into the valley before referring to the garden proper, it is because it possessed the greatest attraction to me. Bosahan House is a fine one, and the plants that drape its walls are reminiscent of the Temperate House at Kew. One of the largest of climbers is Stauntonia hexaphylla, but the collection includes various escallonias, Bignonia capensis præcox, Tacsonia eximia, Rhodochiton volubile, Eccremocarpus scaber, Bignonia australis—very fine—Tetranthera californica, the blue-flowered Australian Sollya heterophylla, the crimson-flowered Mexican Cestrum (Habrothamnus) fascicularis, and Citrus trifoliata. The terrace along the garden front has its flower beds, but more conspicuous are the big yuccas, palms, and dracænas. Round the front entrance, where there is ample room for carriages to come and go, there is a huge hedge of fuchsias (Fuchsia Riccartoni), a gorgeous mass of brilliant colouring in late spring and summer, rising six or eight feet high.

Leaving the house front we proceed to examine the very choice collection of trees and shrubs that Sir Arthur Vivian has brought together. Any and every subject I have mentioned in previous Cornish notes is to be found here, and usually rather finer than elsewhere, although huge rhododendrons are not so prominent as usual. Eucalyptus globulus is 75ft. high. Colletia cruciata is a small tree, while Choisya ternata is represented by huge bushes, and Benthamia fragifera is a common tree. Acacia melanoxylon and A. Drummondi are very fine among many others of their family. The climbing Brachysema lanceolata yields its red flowers all the winter through, and the correas seem never out of bloom. Sutherlandia frutescens thrives unprotected, and so does Metrosideros floribunda, while Indian azaleas are as common as laurels in some gardens. Clethra arborea grows with great vigour, and blooms profusely; the specimen herewith illustrated being twelve feet high, and nearly as much in diameter.

I do not remember whether Sir Arthur Vivian has a catalogue of the plants that are hardy at Bosahan, but if he has it must be a very large one, for my own notes, made during an afternoon visit, could easily be extended to several pages, but it must suffice now for me to mention that Buddleia variabilis is evergreen at Bosahan; Magnolia Campbelli is a fine plant, but has not yet flowered; Pittosporum Mayi, Berberis Knighti, Photinia serrulata, Acacia cultriformis, Hakea saligna, Olea europæa (the Olive), Ceanothus rigidus, Myosporum serratum, P. nigricans, Crinodendron Hookeri, Melaleuca hypericifolia, Drimys Winteri, the curious Plagianthus betulinus, and the Japanese Loquat, most of which we usually regard as greenhouse plants, are finely represented out of doors at Bosahan. Nor must I omit the Lapageria Walk that extends 68 yards along the north side of a high wall, where red and white lapagerias are rampant—no other word suffices, and where on the rustic arches Clematis indivisa lobata is wonderfully fine.

My final reference must be to the dell where bamboos grow with almost tropical luxuriance, and where you feel rather disappointed at not finding a well-tanned Britisher waiting with ready gun for tiger, crocodile, or other fearsome beast. We pass more palms, including a fine pair of Chamærops humilis, an old Trachycarpus excelsa in fruit—the mother plant of many that are planted in the valley; Jubæa spectabilis of good size, and Phœnix canariensis that withstood 10 degrees of frost on one severe visitation. The little pond and stream is completely surrounded by grand clumps of all the now well-known kinds, and within these are splendid masses of Osmunda regalis, giant acanthuses, and huge spreading gunneras. Water lilies, aponogeton and arums flourish in the water, and Sarracenia purpurea flourishes in the boggy ground near by. The bridge over the stream is made of bamboo, so that altogether this is another very un-English scene.

The reader will, I assume, imagine it was not easy to leave beautiful Bosahan, its hospitable and garden-loving owner, Sir A. Vivian, or his very keen gardener, Mr. Rundle, but it had to be, though not before I had signed Sir Arthur's "Garden Book," wherein he secures the signatures of his visitors and a comment from them upon the gardens of Bosahan.



A GLIMPSE OF TREE FERNS AND PALMS AT BOSAHAN.

Tregye.

One of the jolliest little gardens that I saw in Cornwall is Tregye, the home of the Hon. John and Lady Margaret Boscawen. It is a comparatively small garden, designed and made by its owner, and reflecting a great deal of his jollity and breezy manner. Tregye is a short distance from Perranwell, to the south-west of Truro, and there are some hills to climb before you reach it. The house is on high ground, and so situated that when a south-westerly gale is blowing with full force it seems to shiver. But strong as some of these gales are, there is ample evidence at Tregye of the general mildness of the district.

Rarely does one find a house so well clothed with beautiful climbers. Along one side the red and white lapagerias luxuriate and intermingle, reaching right up to the eaves and forming a covering dense enough for birds to nest in. Near by is a fine plant of Camellia reticulata, with scores of its large and gorgeous blooms. The new Jasminum primulinum, close by the front door, was beautifully in flower at the time of my visit, but the great Cassia corymbosa that almost covers one side of the house only suggested the cascade of golden flowers it presents every summer time.

Agapanthuses are a fine feature at Tregye, and crinums are given a warm border, but these latter were badly hit by the severe weather of the winter of 1906-7. Both Mr. and Lady Boscawen are great lovers of daffodils, and they have done very much to create and encourage that enthusiasm for early spring flowers now found throughout the Duchy of Cornwall, and finding notable expression in the fine shows held at Truro and elsewhere.

The daffodils at Tregye are well grown, and they are usually very successful at the leading Southern shows. They are grown in groups and also in rows, and, as is the case with almost every other daffodil enthusiast, there are numerous batches of seedlings. One semi-circular bank full of poeticus seedlings presented a charming picture in the sunshine of a spring afternoon. From these one turned to the batches of such fine kinds as King Alfred, Lady M. Boscawen, Lulworth, Lucifer, White Queen, White Wings, Weardale Perfection, Glory of Leiden, Grandee, Stanley, Maximus, Mrs. Langtry, and many another of equal beauty. Primroses also attract attention at Tregye in the springtime, for they, and polyanthuses, are freely planted. That very fine primrose named Evelyn Arkwright, does well here, and a good row of it, bordering a large group of choice hard-wooded shrubs, carried an abundance of large, beautiful flowers. Another fine primrose, a double one, named Warley Yellow, was, in its way, equally fine.

The group of plants surrounded by the primroses is worthy of more attention than can here be given. It is near the garden front of the house, close to where a little path leads down through a rockery bank from the carriage drive. It is sheltered by a few large trees, and consists of a selection of acacias, several choice rhododendrons, and a collection of boronias and correas. In the ordinary course of things these do well, and flower finely in due season, but now and again there comes a severe winter that may do a great deal of damage among these natives of warmer climes. But Cornish garden lovers willingly take these risks, with the result that their gardens present a totally distinct appearance from those found farther north.

Very short was my visit to Tregye, but it was very pleasant to meet Mr. Boscawen at his home, and to feel some of his enthusiasm for the plants and flowers he has planted, and which he so greatly loves. It was quite different to meeting him "on duty" at the sittings of the Royal Horticltural Society's Daffodil Committee in far away Westminster. Two or three other matters must be noted, however. One is that Fourcroya longæva is a success at Tregye; I do not remember whether it has flowered there, though I know it has done so in the Scilly Isles. Lomaria magellanica is represented by the finest specimen or group I have seen outside the Scillies, and it is a splendid fern when growing freely as in so many Cornish gardens. My last note is of the hardy cyclamens. These are beautiful at Tregye, occupying, in the case of C. Coum, a large area under rather low trees, on either side at the top of a little flight of steps that lead up from the rose beds to the drive. Here, moist and warm during winter and spring, but hot and baked in the bright summer and autumn sunshine, they thrive, flower, and multiply amazingly. Cyclamen hederaceum occupies a somewhat similar position, farther away round a big old tree.

Trewidden.

It was a great disappointment that limitation imposed by steamboat and railway companies gave me but little time to spend at Trewidden. I was persuaded, at Penzance, that Trewidden was "about" a mile along the southern road towards Land's End; it must have been an Irishman who informed me, for I never remember so long a mile as this one. Trewidden is an unusually interesting garden, belonging to T. B. Bolitho, Esq., a gentleman well versed in hardy—or ought I to say half-hardy?—plants, and one who has always a welcome for anyone keenly interested in horticulture. Mr. Bolitho is fortunate in his garden, and also in his gardener, Mr. Maddern, who knows every plant in the garden and discusses names and synonyms in a manner that would do credit to a member of the Herbarium Staff at Kew.

In my Cornish tours I have always been very much interested in the climbing plants used for the walls and to drape the dwelling house. At Trewidden the most notable features in this connection were Rhynchospermum jasminoides, Raphiolepis ovata, Camellia reticulata, Berberidopsis corallina, Cestrum elegans, Acacia cultriformis

Lonicera Hildebrandti, that has flowered out of doors, Jasminum primulinum, Cantua dependens, and the beautiful violet-blue Lasiandra macrantha.

The Trewidden gardens are very smartly kept, and their attractions are many.

A HANDSOME CHAMÆROPS HUMILIS AT BOSAHAN.

Rockwork edgings to the pathways have been made a feature, and there is a charming little rock garden, with pools of water. Erythroniums were finely in flower at the time of my visit, notably E. Howelli, E. Johnsoni, E. Watsoni, E. Hendersoni, E. Dens-canis, E. giganteum. This garden is surrounded by fine rhododendrons, and by the sides of the stream that lead to it a fine lot of phormiums flourish. It is said that tin was first found at Trewidden; the old tin streams and the hills and dells produced in working for tin have been used charmingly for garden purposes, and they provide some delightful peeps and several tree-fern hollows.

Trewidden has its avenue of dracænas, and it also has some splendid embothriums. It is famous for its collection of rare and choice trees and shrubs, all carefully planted and tended, and given ample room to develop. The Chilian Guevina Avellana is over 14ft. high, it has white flowers that are succeeded by edible coral-red berries, and it is a fine plant. Chorozema Lowi is a big bush, and flowers profusely. Magnolia hypoleuca is represented by a very large specimen. Styrax obassia, S. japonica, and Stuartia pseudo-camellia are very fine, and two grand specimens of Skimmia japonica almost fill the garden with fragrance when in bloom in springtime. Escallonias are a feature, and they form a fine protection for other subjects against keen winds. There are several good plants of Crinodendron Hookeri, and of Abutilon vitifolium album. Of the broad-leaved Dracæna indivisa vera there is a plant rather over 10ft. high. Even the rare Feijoa Sellowiana, a Myrtaceous shrub from Brazil, is an outdoor plant of considerable size, and a cocos which I have noted as C. campestris (a name I cannot find) has remained out of doors unprotected for several winters. The Japanese Cæsalpinia japonica produces its yellow flowers regularly every year at Trewidden, and the lovely Eucryphia pinnatifida, rising 20ft. high, must be a beautiful picture when in full bloom.

All these references show how genial is the climate of Penzance and its neighbourhood, and indicate the keen gardening instinct that leads to the formation of a collection of plants that will thrive in such a favourable locality. It may be instanced that Cycas revoluta is never protected at Trewidden, and that for years the lovely Leschenaultia biloba major grew here out of doors, but was killed in the winter of 1906-7, a winter that severely tried many of the choice plants in all Cornish gardens, but did not cause the owners of these gardens to lose faith in the genial climate of the duchy.

Chas. H. Curtis.

TRANSPLANTING ONIONS.

I am well aware that at the moment of writing there are in numerous gardens onion plants already up in the seed boxes and developing into sturdy little specimens, but these are the plants that are intended to give exhibition bulbs, and unless seeds are sown very early in the year it is impossible to produce them of size sufficient to stand much chance on the show table. I cannot say that I have much sympathy with the monster exhibition onion. I will admit that it is a triumph of horticultural skill to grow a bulb which turns the scale at two or three pounds, and if I thought I had a chance of winning a £100 prize with a single bulb, which was the good fortune of a competitor in an onion show at Leamington last year, I might be tempted to try my hand at monster onions, but apart from an exhibition point of view there is little to be said in favour of large bulbs. Commercially and economically they are of little value, and do not pay for the time and trouble spent over them, but then there is an infatuation about size which appeals to gardening human nature, and the man who succeeds in producing the biggest onions in the show takes all the credit unto himself, and not infrequently is envied by his fellows.

Having laid myself open to reproach for daring to criticise the monster show onion, let me hasten to say that the system which produces it, modified to a certain degree, is a good one to adopt in order to grow a heavy crop of bulbs that are useful and commercially valuable. In the first place, in order to grow big onions the cultivation of the ground must be deep and the manuring liberal. Just so, and does this not also apply to ordinary utility crops? It is impossible to grow good onions by merely scratching over the surface soil and wheeling a dung barrow across the beds; but if the ground is double dug, preferably in the autumn, manured at the time and left rough on the surface during the winter, the

A FINE SPECIMEN OF CLETHRA ARBOREA AT BOSAHAN.

top soil crumbles under the influence of drying winds in the early spring and a good tilth is obtained.

Some people change their onion ground every year, but I have proved, and others have done the same, that if the bed is treated annually on the lines suggested above, onions may be grown in the same place successfully for an indefinite period, and the land is brought into a better state of cultivation than if a fresh piece is taken in hand each season. So far as the preparation of the ground is concerned then the treatment for big and medium-sized onions is practically identical, and the next point is sowing.

Considering that in most establishments it is part of the duty of the gardener to grow a good supply of onions, sowing is an item of some importance. Prior to the advent of the big show bulb, all the seed was sown in the open ground, and gardeners who seized the first opportunity for getting in the seed when soil was dry and weather favourable acted wisely, but here again I would suggest copying the exhibitor by transplanting the onions. Mind you we have not two-pounders in view, but useful onions, and the middle of February is early enough to sow the seed thinly in propagating boxes. A saving is effected at the beginning in the smaller quantity of seed required. Moderate heat to germinate the seed and then a position near the glass in a cool house or frame is the treatment required, and by the end of April or early in May the plants are ready to go out. No pricking off is required as the plants can be transferred from the seed boxes to the open ground, this being a way in which the exhibition method is modified. On a favourable day, when the soil is dry, the bed should be raked over and trodden down firmly, and the onions should be shaken from the soil in the seed boxes and planted with a trowel six inches apart in rows a foot asunder. They should be watered in as the work proceeds, and the chief item of cultivation after that is hoeing. I find that when planting it is well to shorten the tops a little or they fall on the ground and are dragged under the surface by worms.

By adopting this method of onion culture the first advantage is economy in seed; secondly, the tedious operation of thinning is avoided; thirdly, a heavier crop of even, medium-sized bulbs is obtained; and fourthly, there is generally less trouble with maggot than when the seed is sown in the open. In a good many gardens the transplanting of onions has completely taken the place of outdoor sowing, and the method commends itself to all and sundry who have the necessary accommodation for raising the plants, which consists of a heated greenhouse or a frame where a little bottom heat is provided to assist the germination of the seed. Boxes deep enough to hold three or four inches of soil should be employed, because in very shallow receptacles there is not much space for the roots, and the onions often assume a yellow and sickly appearance before the time for transplanting.

In the way of varieties, if one's object is exhibition bulbs, an onion of the Ailsa Craig type must be grown, but for utility purposes I prefer one that keeps better. Sutton's A1 is an onion that I have grown for a number of years, and I question if there is a better one for all-round purposes. It is a flattish type, grows to a good, useful size, is mild in flavour, and a splendid keeper. Indeed for autumn as well as spring sowing this variety can be highly recommended.

G. H. H.

GUNNERAS AND WATER LILIES AT BOSAHAN.

ROYAL OR FLOWERING FERNS.

The term "flowering fern" is applied to the osmundas on account of the similarity which exists between their fertile fronds and partially developed flower spikes. The well-known Osmunda regalis, attains to magnificent dimensions in my native county of Devon, often towering up to ten feet in height in very moist and shaded positions. It is essentially a water lover, and thrives in luxuriant fashion by water courses and in swamps that are created by the overflow of lily ponds and water gardens generally. It is, however, necessary to keep the crowns well above the water level in planting, but as regards soil the plant is by no means fastidious, doing equally well in loam, peat, or leaf-soil.

As seen growing in an ordinary hardy fernery, with no special attention paid to it in the way of artificial watering, it rarely exceeds four feet in height, but even here its handsome and very distinct frondage renders it a conspicuous object. When employed in this way I would advise that sites be prepared for the plants, a thick layer of clay being placed a couple of feet deep, followed by retentive loam and short stable manure or leaf-soil; planting should be in a deep cavity in order to facilitate the inundation of the quarters from time to time during their season of growth.

It is interesting to note that the royal ferns, or osmundas, are very widely distributed geographically, being found in the Himalayas, North America, Europe, Brazil, Japan, China, South Africa, etc., and, with the exception of O. r. palustris, they are all deciduous. This variety hails from Brazil, and forms a capital pot plant. The young fronds assume a bright red tint, but later give way to a delicate pale green. O. r. gracilis is of elegant growth and habit and well worth attention, and, on the other hand, we have density in the crested form known as O. regalis cristata. In a species from North America—O. Claytoniana—the central portion of the fronds only are fertile, the upper part being barren, and, as a consequence, it is often found catalogued as O. interrupta.

Japan supplies us with O. r. corymbifera, of small growth, but in spite of this it is strikingly effective, more especially grown in pots, and the same remark applies to O. r. japonica from the same country. O. cinnamomea is a very interesting species, the very narrow fertile fronds being arranged en masse in the centre of the plant, and the spore cases are cinnamon coloured. O. r. purpurescens and O. r. undulata extend the list, the last-named having handsome wavy frondage. O. javanica must not be lost sight of, being of a rich dark green shade.

All the osmundas are distinctly handsome and ornamental, which cannot be said of any other section, either hardy, greenhouse, or exotic, and every amateur should possess a fully representative collection.

Walter H. Agget

Everyone interested in a garden should obtain a copy of the Alphabet of Gardening, by T. W. Sanders. Thoroughly practical information is given as to soils, manures, seed sowing, planting, potting, budding, pruning, grafting, forcing, hybridising, etc., with explanatory diagrams. Price 1s. 6d. net, by post 1s. 9d.; cloth, 2s., by post 2s. 3d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

POTASH.

This is one of the four indispensable plant foods, i.e., nitrogen, phosphoric acid, potash, and lime. Though we do not hear so much about it as about the other three, mainly because there are good supplies in most soils under cultivation, yet it is none the less important, especially in fruit culture. The ash of the wood of fruit trees itself contains a good deal of potash, while of the ash of the fruit it may be said to constitute 50 per cent., taking one fruit with another. Upon the supply of potash in the soil depends the production of sugar in beet, grapes, apples, and other fruits. The colour and flavour of fruit, as well as to a great extent, the depth of green of plants and vegetables and the scent of flowers, are also dependent upon it.

Many soils are naturally rich in potash, and, in the absence of a detailed analysis of a given soil, it may be said that, if in the neighbourhood clover grows luxuriantly, that soil is fairly rich in potash. Dark-coloured garden soil that is under spade cultivation and receiving liberal supplies of stable manure every year or alternate years, seldom needs potash, as such manure contains about as large a proportion of potash as of nitrogen, namely, some ten or twelve pounds to the ton. Clay soils, too, are generally rich in potash to start with, as they are mainly derived from the disintegration of the felspars, one kind of which, orthoclase, contains as much as 16 per cent. of potash. Mica is another potash rock, containing from 5 to 10 per cent. of it. Rocks which contain much of these minerals in their composition—as, for instance, granite, which often contains 5 or 6 per cent. of potash—will, by their disintegration, produce soils rich in potash.

On poor, sandy, or gravelly soils, there is almost invariably a lack of potash, as well as on soils where there has been continuous cropping with little regular animal manuring. There is little or no reserve store of potash in very porous soils, because the constant admission of air to the soil results in the oxidation of the humus which is such a storehouse of this mineral. The following percentages of potash in the top nine inches of typical soils are taken from Mr. A. D. Hall's excellent book on "The Soil," and may be of interest to some in this connection, and a guide to the needs of different classes of soils: Heavy London clay, 1.13; heavy gault clay, .96; clay loam, .33 (subsoil, .67); calcareous loam, .46; light loam (Millstone grit), .2; light loam (Hythe beds), .64; sandy loam (Red Sandstone), .29; and sandy loam (Thanet beds), .35. It will be seen from these analyses that the origin of a soil has a deal to do with its content of potash as well as with its texture. These analyses were all of arable land or pasture, and garden soil on any of these formations which had been long dunged would probably contain higher percentages of potash.

The question that arises is: To what extent is potash necessary in the garden? Obviously, if the above statements are accepted, it is not so generally necessary as nitrogen or phosphoric acid. As regards ground under spade cultivation and regularly manured, there is little likelihood of there being much need for the application of potash, unless the soil is very sandy or gravelly, or otherwise naturally poor in this essential food. The great need of potash is where soil is under continuous and perennial cropping, as, for instance, fruit trees, asparagus, herbaceous borders, etc. It is in such cases that potash is almost invariably necessary. On soils, too, which are frequently and heavily cropped with plants which are great users of potash, such as potatoes and strawberries, this manure often supplies a great need.

Potash may be supplied to growing crops in two ways. First by unlocking the stores of potash already existing in many soils. The addition of lime in any form has a wonderful effect in liberating potash from its compounds. Basic slag on heavy soils has the same effect, while the action of gypsum in liberating potash is greater than either. Good cultivation of the soil and exposure to frost aerates the soil and aids the decomposition of the humus, the resulting acids of which also help to unlock the potash. But for fruit trees, where no proper digging in of animal manure has been possible for years, where the long occupation of the ground by the roots has exhausted the soil of potash, and where, moreover, the application of sufficient dung to afford the necessary supplies of potash might give the trees more nitrogen than was good for them, in such cases the direct application of potash in some form is not only helpful, but necessary for the best results, not only in quantity of fruit but in quality.

The most general form in which potash is applied is that of kainit, which is a natural crude product of the German mines at Stassfurt. It contains from 12 to 12½ per cent. of actual potash, or about 23 per cent. of sulphate of potash, mixed with a good deal of common and magnesium salts. It should be applied during the autumn or winter, so that the chlorides of sodium and magnesium, which are apt to be injurious to the tender rootlets of plants, may be washed from the soil before the spring arrives. For raspberry plantations 2 to 4lb. may be applied to 40 square yards, and for gooseberries and currants 2oz. to the bush. For dwarf apples, pears, plums and cherries, no uniform rate can be prescribed, for if the trees are growing strongly they are best without any, while if getting exhausted, they will be the better for three or four pounds to the forty square yards. Only a light hoeing-in is necessary. Standard trees will generally be the better for it, though one has to spread it over a large area of ground to give them the full benefit of it. Where they have the run of vegetable quarters which are liberally treated they will doubtless help themselves sufficiently, but in a grass orchard kainit should be applied when the trees have been in bearing for some years, at the rate of 2 or 3lb. to 40 square yards. Asparagus may be given with advantage as much as 10lb. to 40 square yards, and the lawn 3lb. Where potash is regarded as necessary for ground under spade culture, 2 to 3lb. to 40 square yards is sufficient for most crops.

Kainit is injurious to strawberries, and yet this fruit benefits considerably by the addition of potash. There are two principal ways of supplying their needs in this matter. One is to supply sulphate of potash in the winter at the rate of 1lb. to 40 square yards. The other way is the liberal application of dung, to which wood ashes have been added. It is said that while 1,000lb. of old poplar wood will only contain ¾lb. of potash, the same weight of bean stalks will contain 20lb., and that of grape vine twigs 40lb. Hence wood ashes are very variable in quality, containing from 5 to 30 per cent. of potash according to their source. To the perennial flower border it would be safer to apply the potash necessary in the same way as to strawberries, kainit possibly damaging the bulbs, which are making their underground growth in the winter.

Another alternative potash manure is muriate of potash, but it might be as well for cultivators inexperienced in the use of artificial manures to leave it alone, as damage is so easily done by it. Like other potash manures it should be applied in the early winter. It is especially injurious to strawberries, and some say it produces weakness in potatoes, though others recommend it.

Like lime, potash has other than manurial uses. One is in regard to the pear midge, a pest which seems to be spreading. The Board of Agriculture, in their leaflet, recommend the application of kainit at the rate of 20lb. to 40 square yards in June just before or immediately after rain, this having the same effect upon the bodies of the larvæ as lime upon slugs. If grass is under the trees, it is recommended to cut it very short before applying the kainit.

Kainit is very cheap, 50s. to 55s. per ton, while sulphate of potash may be as high as £10 to £11 per ton for the highest grades, the percentage of potash ranging from 20 to nearly 50 per cent. of actual potash. Muriate of potash contains from 50 to 55 per cent. of potash, and the price is about £10 per ton. Local dealers will generally supply it in 2cwt. bags at per ton rates if they keep it in stock, or if they can get it down by rail with some other consignment.

Alger Petts.

THE USEFUL LEEK.

I have no intention of writing an article on the cultivation of leeks, as everybody is acquainted with the method, and no vegetable crop is more easily managed. My object rather is to persuade people to grow more leeks which, at the present moment—the beginning of February—is proving its value. Both in markets and gardens greenstuff is scarce, the dry summer of 1908 was not favourable for its development, and the moist and mild autumn caused sappy growth, so that although the winter has not been severe, members of the cabbage tribe have not stood it well. Many people are getting towards the end of their onions, and the price asked for this commodity proves that the supply is limited. With the supply of vegetable stuff more or less short, leeks step into the breach, and in this crop we have a hardy and useful vegetable to fall back upon, and what many would have done without leeks this year it is hard to say. The fact that the plant is so accommodating perhaps accounts for it not receiving the treatment it deserves, and the bunches of wiry, thin specimens that are offered in the market and command ready sale are mere apologies for good, well-blanched leeks.

While we are enjoying this wholesome vegetable now, and wishing, in many cases, that better specimens could be obtained, the moment is opportune for thinking about this time next year, and sowing a pinch of seed in a box under glass to provide a few early plants. To get good stems a long season of growth is required, and in addition to this plenty of manure. The general way of growing leeks is to plant them in shallow, well-manured trenches, adding earth as required to bleach the stems: but good leeks are also grown by making holes in well-manured ground with a thick, blunt dibber, dropping the little plants in the holes with only the upper leaves protruding above the surface, and pouring a drop of water into the holes as planting proceeds to wash the soil round the roots.

So much for methods, and in conclusion I would emphasise the advice given at the beginning to grow more leeks, the extreme usefulness of which more than one has proved this year.

H.

BURMESE LILIES.

The announcement in the advertising pages of the Gardeners' Magazine of a large consignment of Lilium sulphureum (which has proved to be the most accommodating of the Burmese lilies), carries one's mind back nearly twenty years, for on June 25, 1889, this species was given a First Class Certificate by the Royal Horticultural Society. Great was the interest at that time centred in this lily, the appetite of lovers of this beautiful class of plants having been whetted a year previously by the distinct and charming L. nepalense from the same region.

Lilium sulphureum was first exhibited and distributed under the name of L. Wallichianum superbum, this last name having been given it by Mr. Baker, of Kew. Subsequently the same authority saw fit to reconsider his decision, and assigned it specific rank as L. sulphureum. It is in every way a grand lily, the dark-coloured bulbs being compactly built, and the stem pushed up therefrom is stout and very thickly clothed with narrow leaves. As with many other lilies the leaves increase in width toward the upper part of the stem. This latter will reach a height of six feet, and often considerably more. A notable feature is the presence of bulbils in the axils of the leaves, such as are to be found in Lilium tigrinum.

The flowers are of a deep cream tint heavily tinged with yellow in the interior, while the outside is sometimes flushed with red. The petals are of a thick wax-like texture, and the flowers are sweetly scented. As a rule, this flowers towards the end of the summer, and in autumn. For this reason it is, unless in the southern part of the country, more adapted for the embellishment of the conservatory than the open ground. Fine examples were last autumn to be seen in No. 4 greenhouse at Kew, some in pots and others planted out in a bed with camellias, etc., these last being very finely developed.

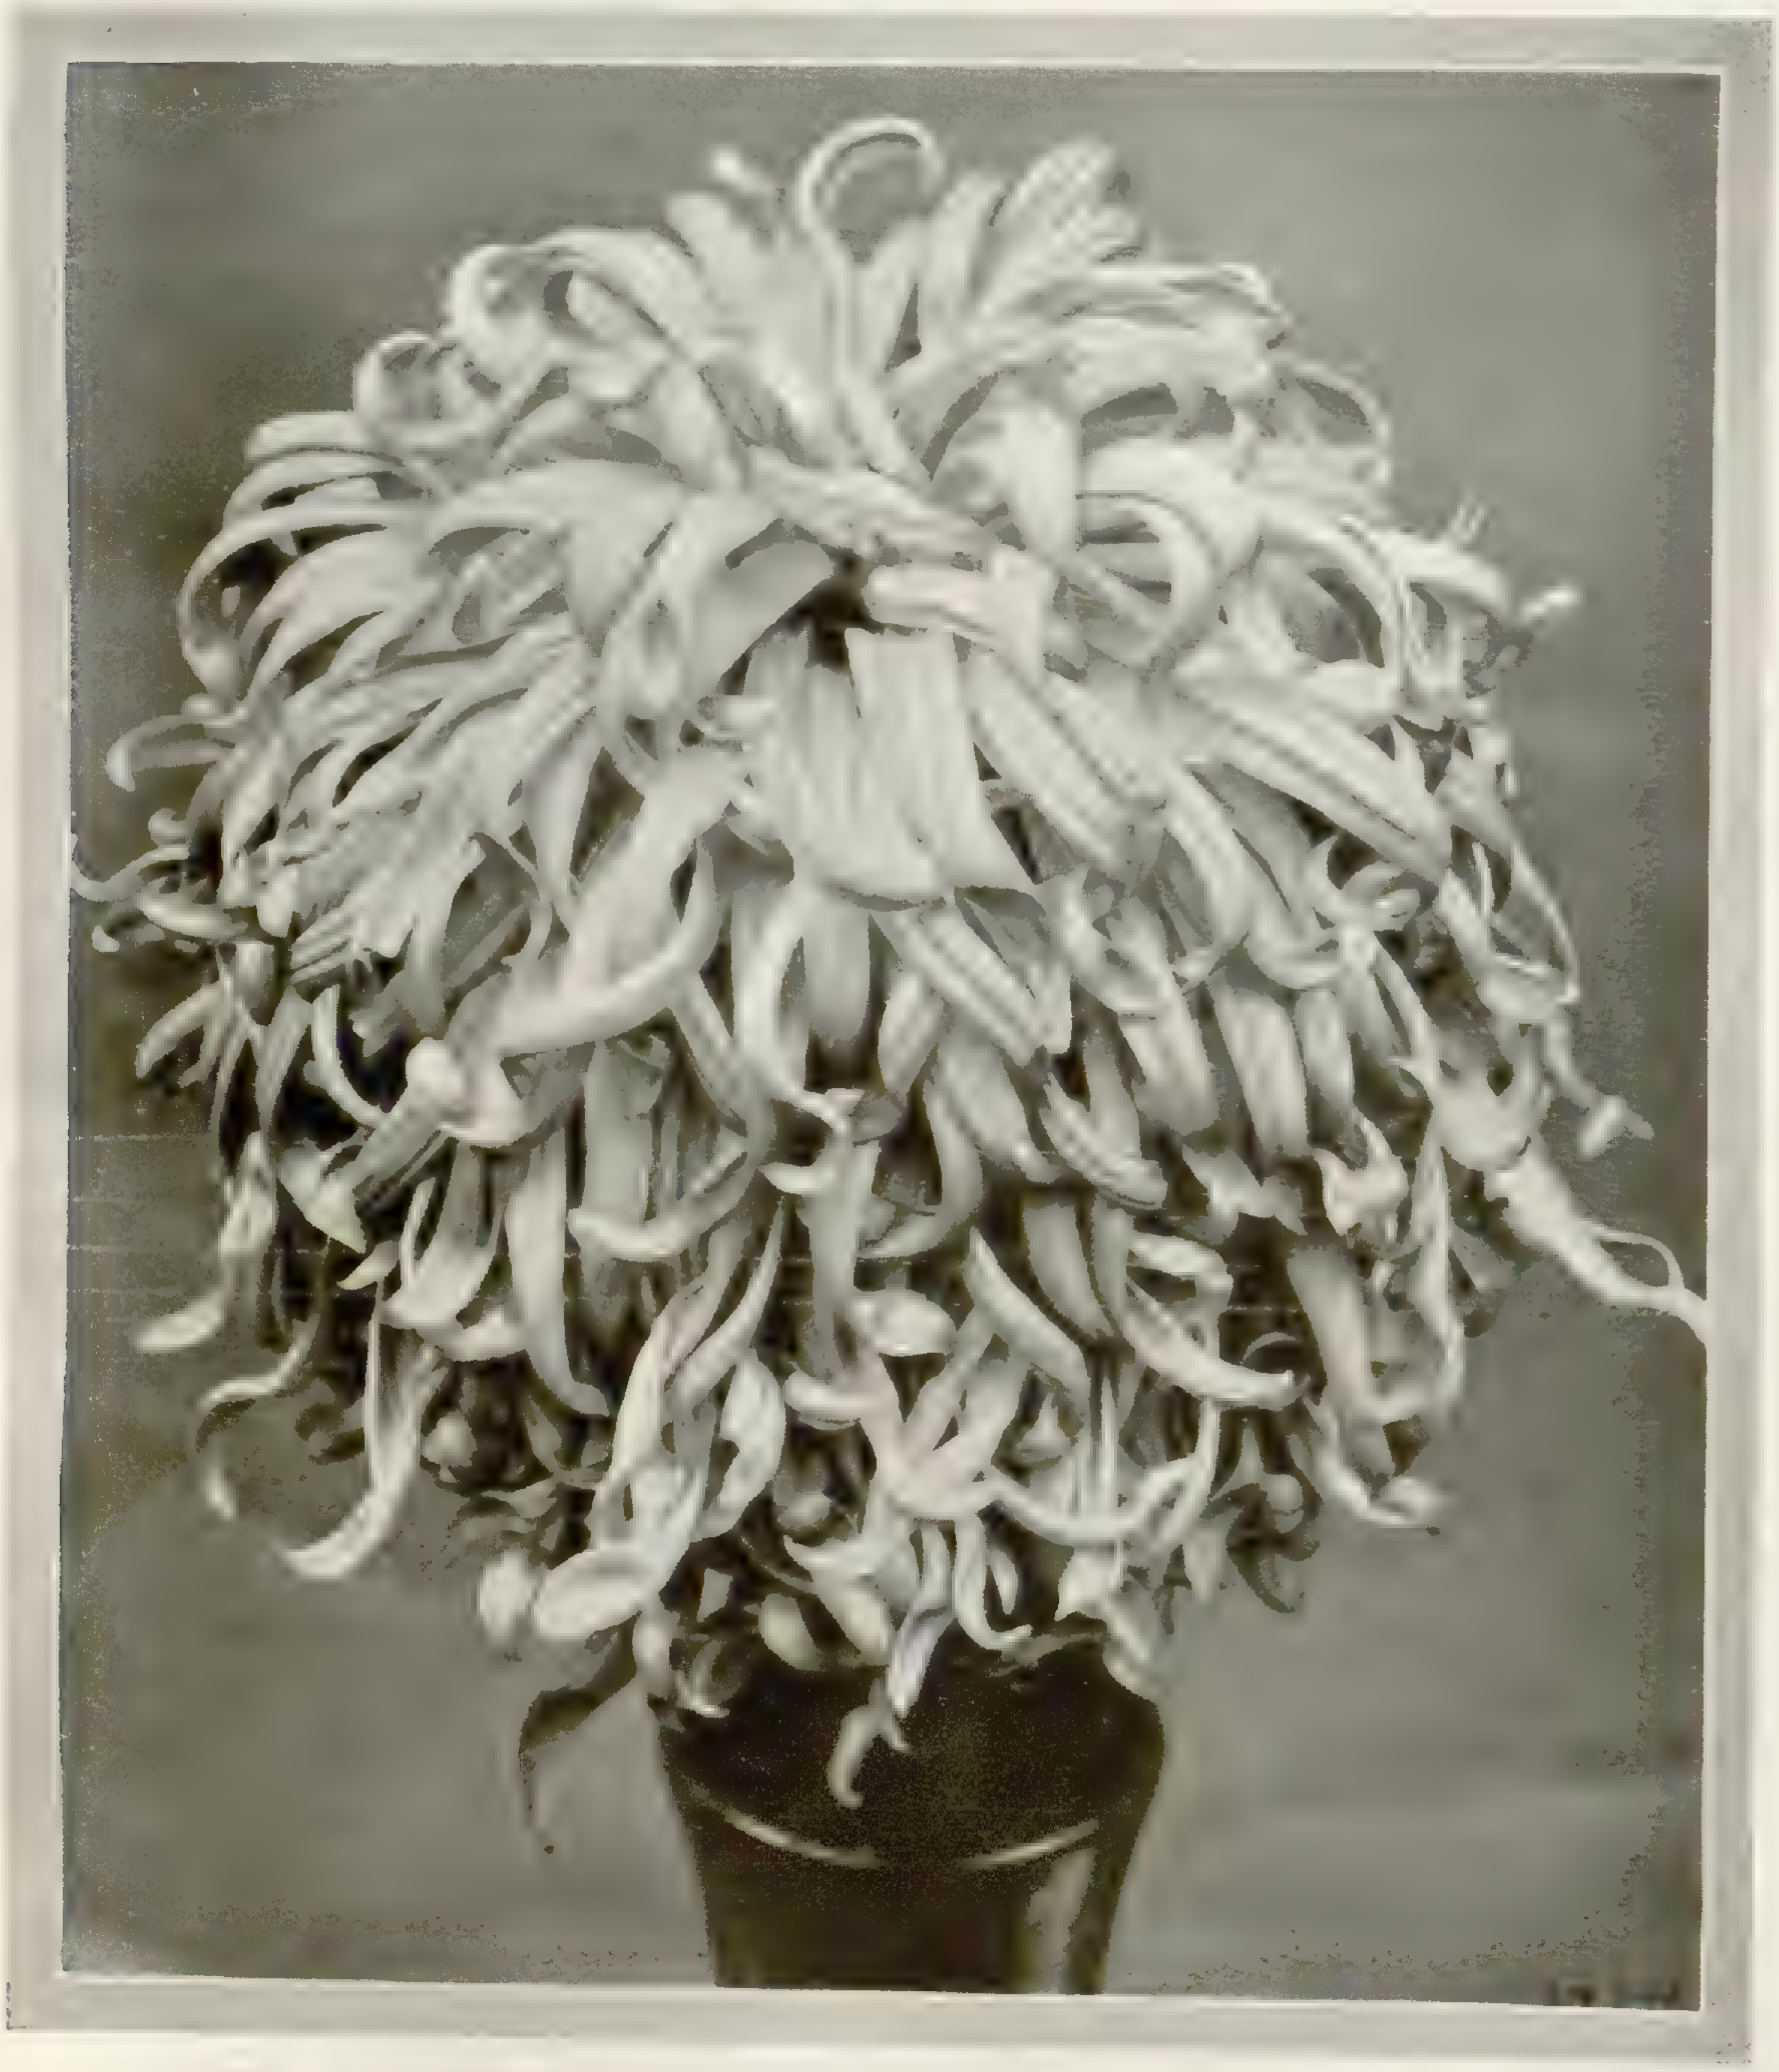
Lilium nepalense occurs in Upper Burmah, being found sometimes associated with L. sulphureum. It does not, however, succeed so well under cultivation in this country. The introduction, or perhaps reintroduction, for it is said to have been previously grown in this country, occurred in 1888, and I question if any species since L. auratum came over has attracted so much attention as did L. nepalense on September 11, 1888, when it was first shown in flower by Messrs. Low and Co., and a First Class Certificate was awarded it. The colour of the flowers is yellow, or greenish-yellow, with a chocolate-purple centre. There is, however, a good deal of individual variation in this lily when grown in quantity.

Lilium Bakerianum (syn. L. Lowi), the third of the Burmese lilies to mention, is quite distinct from the two preceding. It is more delicate in constitution, and pushes up a slender stem to a height of two to four feet, or sometimes a little more. This stem is rather sparingly furnished with narrow leaves. The flowers, which vary somewhat in shape and colouring, are bell-shaped, with the segments more or less reflexed. They are white, shaded with green on the outside, and in the interior spotted with crimson. This spotting varies considerably in the density and size of the spots; in some individuals the colouring is run together into fair-sized blotches. This lily was introduced somewhat later than the two species previously mentioned.

Lilium primulinum, another of the Messrs. Low's introductions, was first shown under the name of L. claptonense This was in the autumn of 1891, and I fear that since then this pretty lily has been lost to cultivation. It is (or was) in general appearance a good deal like L. nepalense, but the flowers are of a clear unspotted yellow tint.

While on the subject of these lilies a word may well be spared for the Neilgherry Lily (L. neilgherrense), which, 20 to 25 years ago, was sent to this country in considerable numbers, but of late years it is rarely seen. Though imported bulbs flower freely the first year, they quickly deteriorate, so that in order to keep up the supply constant importations are necessary.

W. T.



NEW JAPANESE CHRYSANTHEMUM HON. MRS. LOPES.
Raised by Mr. M. Silsbury, Shanklin. Flowers very large, but much reduced in illustration: colour bright yellow.

CHRYSANTHEMUM HON MRS. LOPES.

Prominent amongst the more noteworthy of the new chrysanthemums introduced to public notice in November last was the Hon. Mrs. Lopes, of which a characteristic illustration is herewith given. The variety, as will be seen from the illustration, belongs to the Japanese section, and was raised by Mr. Martin Silsbury, Shanklin, Isle of Wight, who, as so well known to chrysanthemum growers, has been successful in raising a considerable number of Japanese varieties of great excellence. The blooms are of the largest size and of great depth, and they are remarkable for their elegance and bright yellow colouring. While a valuable addition to the varieties suitable for exhibition, it should prove most useful for conservatory decoration and the supply of cut flowers. It may be added that a First Class Certificate was conferred on the Hon. Mrs. Lopes by the National Chrysanthemum Society at its November exhibition, and that an Award of Merit was made in its favour by the Floral Committee at the meeting of the Royal Horticultural Society, held November 10, 1908,

Scabiosa alpina.—Nowadays the perennial scabiouses are best known in gardens because of the really fine Scabiosa caucasica, although it also is not so popular as it was for some years after its general introduction to British gardens. The scabious which I desire to notice at the present time is, however, one quite different from that which hails from the Caucasus, and is a neat little alpine flower, with but little resemblance, save in the form of the flowers, to S. caucasica. It is a dainty little flower, however, having greyish leaves and heads of pretty blue flowers, with all the characteristic form which makes these scabiouses so distinct from almost all other hardy flowers. It only grows some six inches high, and blooms from June to September, so that it is a plant not unworthy of the favour of those who appreciate rock plants, and who are desirous of extending the time when their rockeries look attractive because of their flowers. At such seasons as June, July, and August there is a decided falling off in the number of rock plants in flower, and this scabious will then be found valuable.—S. Arnott.

MENDELISM AS APPLIED TO SWEET PEAS.

The following admirable article, by Mr. William Cuthbertson, J.P., is reproduced from the pages of the "Sweet Pea Annual," by the courtesy of the National Sweet Pea Society:

Prior to the advent of Countess Spencer sweet pea it was universally recognised that the stocks of new sweet peas put on the market by Mr. H. Eckford and others were fixed absolutely. How was this achieved? Many will be prepared to say at once it was on account of the Eckford type being much easier to fix than the new waved or Spencer type. This is only part of the truth. Mr. H. Eckford took infinite pains, and grew his novelties many years before offering them. The same care would have purified and fixed many of the recent Spencer introductions. Mr. J. S. Eckford once informed me that Dorothy Tennant required nine years' work before he and his father considered it fit to offer.

By the way, there is an unwritten chapter in connection with Countess Spencer which I hope Mr. J. S. Eckford will one day write, as it has a bearing on this question of fixity. The year following the introduction of Cole's Countess Spencer Mr. Eckford put on the market a stock of Countess Spencer raised at Wem, which was practically fixed—over 90 per cent. of it came true and remained true. It could not have been Cole's Countess. What was it? What was its pedigree?

In a recent issue of his catalogue Mr. Unwin says: "The Spencer type, which is so much abused for its sportiveness, is every bit as easy to fix as the old plain type, but it requires time." Ay, there's the rub. It requires time. It requires more. It requires knowledge. Mr. Unwin breathes the atmosphere of Cambridge, the British home of Mendelism, and I imagine he applies the laws of Mendel to his work, and hence his success in securing fixity. Those of us who have studied Mendelism and applied the principles to practice have, like Mr. Unwin, become convinced that the fixing of new varieties can be done effectively and within the compass of four or five generations. Working up sufficient stock to enable one to place a new variety on the market is quite another matter. I am asked by the hon. secretary to explain briefly, as a practical grower, the application of Mendel's laws to the raising of new sweet peas. I quite appreciate that some members of the National Sweet Pea Society understand these laws as well as I do, possibly better, but I also recognise that among the 800 members of our society there must be many hundreds who have not had the time or opportunity to study Mendelism.

Gregor Johann Mendel was born in Austrian Silesia in 1822, and died at Brunn in 1884. In 1843 he entered an Augustinian foundation, four years later he was ordained, and ultimately rose to be Abbot of Brunn. When a young man he studied natural science for some years at Vienna, doubtless because the bent of his mind lay in that direction. After returning to his life's work at Brunn he carried out in the gardens of the Cloister the experiments and observations which have made his name famous. It was in a lecture to the Natural History Society of Brunn that he first gave an account of his work. A report of the lecture was published in the "Transactions" of that society in 1864, and received no further attention until it was discovered, or rather rediscovered, in 1900 by some eminent scientists. Very shortly thereafter a translation of it was published in the "Journal" of the Royal Horticultural Society, with an introductory note by Mr. W. Bateson, M.A., F.R.S., of Cambridge, who is the leading British exponent of Mendelism. It is a remarkable fact that a lecture so far reaching in its importance should have been so long overlooked, and it is a sad thought that its value was only appreciated after Mendel had been in his grave for sixteen years.

To illustrate the underlying principles I cannot do better than re-state briefly one of Mendel's now classical experiments with garden peas. He discovered that there are several characters in culinary peas which are distinct and separable, e.g., tallness and dwarfness, yellow seeds and green seeds, round seeds and wrinkled seeds. If we take the first pair as an illustration we find that a pea six feet tall fertilised with pollen from a true dwarf, one foot high, gives in the first generation nothing but tall plants. If the cross is reversed—a dwarf fertilised with pollen from a tall—the result is the same. It is well known that peas fertilise themselves, and are not liable to interference from insects. The plants of the first generation being, therefore, allowed to ripen seed, and that seed being sown the following year gives results as follows: 75 per cent. tall plants, 25 per cent. dwarf plants. It is only necessary here to say that the dwarfs remain true and fixed in future generations, while a proportion only of the tall ones do. To find out which of the tall ones are true talls they must be grown on, and those plants which do not give dwarfs in the next generation are fixed talls. Let me try to explain this clearly as follows:

TALL x DWARF.

Result, one pod containing six seeds.

First Generation.—Six plants, all tall, producing in all, say, 600 seeds.

Second Generation.—Six hundred plants, about 150 of which will be dwarf, and about 450 will be tall. Save the seed of the individual plants separately. Sow next season in short rows.

Third Generation.—Six hundred rows, 150 of which will be the produce of the 150 dwarf plants, as above, and all of which will be true, i.e., giving dwarfs only. Then 150 rows will give nothing but pure tall plants, but to make certain of their purity they ought to be saved separately, and grown again in the fourth generation.

The remaining 300 rows will break up, giving results similar to those obtained in the second generation.

This illustrates the law underlying crossing, discovered by Mendel, as it applies when one pair only of characters is concerned. It becomes much more complex, of course, when several characters are embodied in the cross. How valuable it is to the raiser of sweet pea novelties is quickly becoming understood. It is important to realise at the very outset that results on Mendelian lines can only be expected when pure varieties are operated with, though there is always a liability even with apparently pure types to obtain unexpected combinations or variations.

As to colour, white x cream gives white in the first generation. Red x white gives red in the first generation. Blue or purple x red, or any other colour, gives blue or purple in the first generation. These crosses reversed give the same result in F 1 (i.e., the first generation). In Mendelian language the colour which suppresses the other one and appears in the first generation is dominant. Just as the tall pea is dominant over the dwarf one. The colour which is lost is said to be recessive. The plants of the first generation being allowed to seed, the seeds are saved, the produce of individual plants being kept quite separate and distinct. Sown out the following year the produce appears in almost true Mendelian ratio, thus: Crimson x white gives 75 per cent. crimson, and 25 per cent. white. The marvel, of course, is that the white character of type is carried through the first generation in a latent form to appear in absolute purity in the second, or F 2, generation,* and the same rule applies as in the culinary peas, the recessives, i.e., the whites in this case, breed true, whereas the reds only do so in a proportion of 25 per cent. This is again an experiment in mono-hybridism as only a single pair of characters are in question, namely, the two colours, red and white.

(To be continued.)

---

* To make this clear. The cross is made and, say, one pod containing six seeds is the result. Those seeds are sown the following year and the plants produced are the first or F 1 generation, next year's plants being F 2, and so on in the direct line of descent.

WORK FOR THE WEEK.

◆

THE ORCHID HOUSES.

SEEDLING ORCHIDS.—The principal aim of all who are interested in the raising of seedling orchids is to encourage the young plants to grow as rapidly as possible from the seed bed onwards, so that they may be strong enough to bloom within a reasonable period. It is not many years since when from eight to ten years was considered a reasonable time for seedling orchids to reach their flowering stage. Now we proceed at a more rapid pace, and I am afraid that some of the prominent orchid hybridists would hardly be satisfied if they could not secure three generations of plants within the period above mentioned. Methods and experiences have all assisted the orchid hybridist in the development of this work, and the result is evident on every side in the popularity and more general cultivation of seedlings. The subject of seedling orchids must, of necessity, be included amongst the notes on the general work of the orchid house. Every encouragement should be given to enable the plants to make rapid growth. If young seedlings of any other class of plants become starved or neglected it is generally considered that they are more or less seriously affected, and unsatisfactory results are anticipated. It is just the same with the seedling orchids. I have not the least hesitation in saying that the long period that elapsed between seed sowing and flowering a few years ago was the result of the endeavour to exactly imitate Nature, and give the seedlings a growing and a resting period. The seedling orchids, under artificial conditions, must be treated in a similar manner to bulbous plants raised from seed, and maintained in an active growing state until they reach the flowering stage. One who has charge of quantities of seedling orchids of the different genera needs to be constantly on the alert, not only to provide the necessary conditions of temperature, etc., but also to see to the necessary and constant repottings. Plants taken from the seed bed in the autumn and late summer months should have made such growth progress by the present time as to require more pot room. With the lengthening days and the more favourable conditions prevailing outside this work should be attended to without delay. Plants in a more advanced state of growth may also have any necessary repotting requirements attended to. This will afford full opportunity for the plants to derive every benefit from the summer season as it advances. In the case of all epiphytal kinds I consider a loose, light compost the most suitable. There can be no doubt that a compost of two parts broken oak leaves and the remaining part of peat and chopped sphagnum, with sufficient sand added to render the compost free and porous, is in every way suitable for the cattleya family in the early stages of growth, giving a more solid potting material as they reach the flowering stage. Cypripediums in the earlier stages do best in a compost of about equal parts of peat and chopped sphagnum, with a little loam added after the first three or four leaves have developed.—H. J. Chapman, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

CONSERVATORY AND GREENHOUSE.—Where permanent creepers are planted in beds of soil in the conservatory, the present is a very suitable time for giving them attention. In many cases they may be cut hard back, this applying to such plants as fuchsias, bougainvilleas, tacsonias, passifloras, and cobæas. If the plants have been infested with insect pests, such as mealy bug, red spider, or thrips, stringent measures must be adopted for the purpose of eradicating them. A thorough cleansing with one or other of the approved insecticides will be beneficial, and, where the roof has been partially covered, it will be well to give it a thorough cleansing about this time. If painting has to be done, this will be quite the most convenient time of the whole year. The climbers will, of course, be first pruned. Where part of the conservatory is utilised as a cool fernery, a thorough overhauling will be necessary. All dead and decaying fronds should be cleared away, and where some of the stronger-growing kinds, such as Pteris tremula, and some of the varieties of nephrolepis have outgrown their allotted space, they should be cleared out, and replaced with younger plants. Give the rest of the plants a general top-dressing of prepared soil, to which a little manure has been added.

PALMS AND LARGE FERNS that require re-potting or re-tubbing should be undertaken at once, and, in the case of palms, do not stint the ramming process, as, if potted lightly, the roots are very apt to raise the balls out of the pots.

PELARGONIUMS.—The present is a very suitable time to put in a batch of cuttings of zonal pelargoniums for autumn and winter flowering, and these will be found to root freely if put singly in thumbs in any house where a medium temperature of about 50 deg. is maintained, giving them a spraying overhead occasionally. Young plants, rooted in the autumn and intended for summer blooming, should now be shifted into the pots in which they are to flower. This advice applies also to the scented-leaved, ivies, and also to the show, fancy, and regal varieties. The latter I find especially useful, the colour generally being so soft and pleasing that they are much liked as cut flowers for the table.

POT ROSES.—The latest batch of these should now be brought inside, and may be pruned practically at once. If hybrid perpetuals, they should be pruned hard back, but the teas and hybrid teas should be less severely pruned. Roses that were introduced into heat early in December will be showing their buds, and should receive every encouragement towards the perfecting of their blooms, which are so highly appreciated early in the year. With the longer days the temperature may be raised a little, and the plants may receive one or two dressings of artificial manure. There is nothing I like better than Peruvian guano for them, giving it rather weakly in the water. Beware of cold draughts, as the young foliage is very susceptible to mildew.

FORCED PLANTS.—Continue to bring the forced plants and bulbs forward as they are required, bearing in mind that narcissi, tulips, etc., will not require so long to come into bloom now as was the case a few weeks since, and it may be found advisable to put a batch of stuff into a frame somewhere out of the sun, in case a late batch is required. In this way the bulb season may be somewhat prolonged, and it is better to keep them back now than to try and keep them when well in bloom.—THOMAS STEVENSON, Woburn Place Gardens.

THE FLOWER GARDEN.

PENTSTEMONS. — The improvement which has been effected in the pentstemons during the past few years, both as regards larger and improved shaped flowers and the great increase in the variation in the rich colours, have combined to make them immensely popular at the present day. By making a good selection, and treating them liberally, they produce a wealth of blossom throughout the summer, and, indeed, until late in the autumn. Consequently they are most suitable for growing in borders either wholly devoted to them or mixed with other plants, and they are extremely effective when arranged in beds consisting of one colour in the flower garden. Pentstemons can be successfully raised either from cuttings, which should be taken during the autumn, or from seed sown early in the year. By sowing the seed at once in a light sandy soil and placing it in heat germination will soon take place. When the strain is a good one flowers high in quality and effective in colour will be obtained, and very frequently some fine novelties will result. Cuttings which were rooted during the autumn of last year in unheated frames ought now to be potted up singly into three-inch pots, and be returned to the frame. These will be much improved if the points of the growth are pinched out after new root action has commenced. There are many beautiful named varieties which should be included in all collections where they are grown in considerable quantities. The beds and borders to be devoted to them should be deeply dug, or, better still, trenched, working in a good quantity of half-decayed farmyard manure, and it is well to point out here that pentstemons ought not to be grown on the same site two years in succession.

PERENNIAL PHLOXES.—These, like the pentstemons, have, during the past few years, come much into favour. The old mauve colour, which at one time predominated, has now been superseded by such charming varieties as Miss Pemberton, Coquelicot, Tapis Blanc, Aurora, Solon, and Tom Welch. Their charming colours and the delightful fragrance render them most welcome in any garden. The most successful way to treat the herbaceous phloxes is to pull them into quite small pieces at this season, and either plant them in batches where it is intended they should flower, or put them in three-inch pots, and bed out later on. Potting them is the best where slugs abound and the varieties are scarce. Plant them out the end of next month, but to ensure success it is most imperative that the soil be deeply worked and heavily manured.

DELPHINIUMS.—These are among the most stately blue flowers we have, and, in my opinion, are not sufficiently made use of in grouping them in various parts of the garden. They lend themselves equally as well to arrangement in groups in the shrubberies. Delphiniums may now also be propagated by taking off side shoots and potting them up. The best named varieties should be grown in preference to chance seedlings where only a limited number can be cultivated. Old stools which are intended to remain should receive a good surface dressing of half-decayed cow manure.

SWEET PEAS.—These should now be sown four or five in a three-inch pot, and started in a very gentle heat. Sow also tuberous and fibrous-rooted begonias, Pyrethrum Golden Feather, verbenas, wigandias, foliage solanums of sorts, and dahlias, etc. —E. BECKETT, Aldenham House Gardens.

HARDY FRUITS.

PEACHES AND NECTARINES.—If these were treated during the past season as regards disbudding, etc., as advised in last year's calendar, very little pruning should now be necessary. Remove the trees from the walls, and if not previously done, cut away all the old fruiting wood and refasten the trees in their positions, keeping the young growths from four to six inches apart. Be careful to allow plenty of room for the natural enlargement of the branches during the coming season. If it is found necessary to shorten any of the young fruiting wood, either because of weakness or to prevent overlapping, always endeavour to prune to a triple bud, as the centre one, being a wood bud, will ensure a supply of sap to the young fruits which may set on the shoots so shortened. Red-spider is one of the worst pests that infests the foliage of the peach and nectarines, and we find nothing better for keeping this in check than occasional spraying during the summer months with an emulsion made by dissolving one oz. of liver of sulphur in a little hot water, and boiling 1lb. of soft soap, which, when ready, we pour into a vessel containing ten gallons of soft water; then add the liver of sulphur, give a good stirring, and the whole is ready for use. Spray the trees after the sun has ceased to shine on them.

MANURING AND TOP-DRESSING.—As soon as pruning and training are completed and all rubbish cleared away and burnt, remove any light material, such as the old mulching, from fruit borders, and give the surface a dressing of some approved fertiliser, afterwards lightly pointing it in with a garden fork. If extra soil is required to cover the roots, mix up the following, and place a thin layer over the borders where the roots are found too near the surface, viz., four parts good turfy loam, one part horse-droppings or good rotten manure, and one part wood ashes. For stone fruits, add one part finely broken-up lime rubble. A good manure for such fruits as apples, pears, plums, currants, and gooseberries, on soils which are deficient in lime, is a dressing during the winter of basic slag and kainit sprinkled evenly over the surface as far as the roots extend, at the rate of four ounces of the former and two ounces of the latter to each square yard.

MULCHING. — As the season advances, fruit trees on walls require a large amount of attention, which necessitates a good deal of treading on the borders. A dressing of light strawy manure spread over the surface will add much to the convenience and cleanliness of the work of fixing the necessary protection, etc. The usual mulching with good rotten manure I prefer to leave until after the fruits have set.

RASPBERRIES.—If not already done, let the surface soil in the alleys be very lightly pricked over with the fork, gathering up at the same time all weeds and other rubbish, give the quarter a good sprinkling of fresh lime, following this with a liberal dressing of some well-decomposed farm-yard manure.

BLACKBERRIES AND LOGANBERRIES. —Cut out last year's fruiting canes, and tie up to the supports sufficient young ones for this season's fruiting. Both these fruits are gross feeders, and a good mulching of manure placed on the surface as far as the roots extend, will prove of great benefit to the plants later on.—GEO. WOODGATE, Rolleston Hall Gardens.

PARROTIA PERSICA.

Parrotia is a genus of Hamamelideæ closely allied to hamamelis, a shrubby genus recognised by its bright golden spidery-looking blossoms, which are borne during late autumn or winter. Two species only are known, the second one being P. Jacquemontiana. They are quite distinct plants, possessing few points of resemblance, except, of course, botanically. P. persica is of Persian origin, and is known under the common name of iron tree, a name given on account of its exceedingly hard wood. The flowers are small, but borne in great profusion during January and February. Their attractive feature is their bright red conspicuous stamens, which, on a sunny day, light the whole plant up with a ruddy glow. Another period of beauty occurs in autumn, for at that season the ovate or oblong leaves take on a brilliant orange, orange-scarlet, or red hue. Under normal conditions it assumes the proportions of a small tree, but is also met with in bush form. It is not fastidious with regard to soil, and thrives in comparatively poor ground. Although it has been known in English gardens for upwards of half a century, it cannot be called common, and is rarely met with outside scientific collections.

Index to the "Gardeners' Magazine," 1908.—Those readers who have preserved the 52 numbers of the GARDENERS' MAGAZINE for 1908 with a view of having them bound for future reference, can obtain Handsome Cloth Binding Cases from the publishers, 148 and 149, Aldersgate Street, London, price 2s., post free. The index, with title page, is now ready—price 2d., or by post 2½d. The volume bound complete may also be had, price 12s. 6d., by post 13s. 4d.

THE ROYAL COMMISSION ON AFFORESTATION.

Considerable interest is being evinced in Scottish forestry circles in that section of this Commission's report which relates to afforestation. With the knowledge that this Commission was appointed with a view to the discovery of means of relief for the present distress in schemes of shore reclamation and forestry works, the chief feature which strikes the practical Scotsman is the fact that the bulk of the unemployed are in England. and the bulk of the land suitable for tree-planting is in Scotland. One can hardly help remarking that the Commission's report simply tells us what we were all perfectly aware of before. It is simply a re-statement of the case for afforestation, which has for a good many years past been pressed upon the public attention by those having an intelligent knowledge of and interest in the matter. Where, in the opinion of Scottish experts, the report fails, is in the treatment of the question of how the scheme or schemes of afforestation it recommends are to be conducted.

Apparently it is contemplated that the whole business is to be taken in hand by the State, and certainly it is impossible to see that anything like what is required can be accomplished apart from State action of some sort on a very extensive scale. Among the recommendations or conditions they specify there is one in which the Commissioners say that "any scheme of national afforestation should be on an economic basis." That is all right enough, but then what are we to make of what follows, which is that the taxpayers of the country are to be made to pay the interest on the capital expenditure to be incurred in the afforestation of nine millions of acres which it is proposed to deal with? One cannot help saying that there does not seem to be much of an "economic basis" in a scheme which requires to be financed in this fashion. We are also told that the forests will be more than self-supporting after the fortieth year. Does that mean that the charge upon the taxpayers of the country will then cease?

But there is another and a greater obstacle to the institution of schemes of afforestation in Scotland on any extensive scale, and that is the passion for sport which so largely determines in these days the manner in which much of the land suitable for tree-growing in Scotland is used. In the Highlands of Scotland there are huge areas suitable for that purpose which are meantime reserved for sporting purposes, and so long as the owners of such lands can obtain large ready-money rents for them without having to spend anything in planting or other estate outlays, it is hopeless to think of anything considerable being done in the way of their afforestation until the matter is taken up by the State. A beginning was made in this direction a year or two ago by the purchase of the Inverliever estate in Argyllshire by the Government for forestry purposes of an experimental and educational character, and as public opinion is ripening, it may not be long before we see further action towards the establishment of a system of State forestry in the Highlands of Scotland and elsewhere.

But as to how far the passion for sport and the devotion of great areas of possible timber land to its gratification are to be checked by anything short of the entire expropriation by the State it is not easy to see. Even regarding the existing woods of the country, we all know how many landowners sacrifice their own woods for the sake of the game. That the management of existing woods might be improved enormously all who take an intelligent view of the question are quite well aware. At present these woods are handed over to what the forester thinks the most injurious thing in the country—the gamekeeper. The fox is kept down, but the great enemy to British woods, the rabbit, is allowed to increase.

As a contribution to the public discussion of the question of afforestation the report of the Commission will be useful, if not in the views expressed in it, yet as helping to centre attention on the question of State action in the matter of afforestation. But it does not imply much guidance on the question of the unemployed. All that can be said on that head is that, while the Commissioners rightly insist on the importance, which is already widely recognised, of afforestation as a means of extending employment in the rural parts of the country, and so helping to stay the migration of the people to the towns or to the colonies, it offers no suggestion of practical value as to how the present unemployment in the towns is to be remedied, or how the recurrence of such unemployment is to be prevented.

Aberdeen. W. Kelly.

NAMING OF MULTIGENERIC ORCHID HYBRIDS.

In view of the fact that the raising of hybrids connecting many genera of orchids is now probable (one hybrid connecting four genera is already in existence, and there is no apparent reason why others should not be raised combining all the genera in the respective groups—see list appended), the Orchid Committee of the Royal Horticultural Society of Great Britain believes that the time has come when some definite system of nomenclature, which shall be at once simple, euphonious, and distinctive, should be adopted, internationally if possible.

A sub-committee, consisting of the following gentlemen was therefore appointed by the council to consider the question:

Mr. J. Gurney Fowler (chairman of the Orchid Committee), Messrs. N. C. Cookson, de Barri Crawshay, J. O'Brien, V.M.H., and H. J. Veitch, F.L.S., V.M.H. (members of the Orchid Committee), with Dr. A. B. Rendle, M.A., F.L.S., Messrs. E. A. Bowles, M.A., F.L.S., F.E.S., W. Fawcett, F.L.S., C. C. Hurst, F.L.S., A. Rolfe, A.L.S., and F. J. Chittenden, F.L.S. (secretary), (members of the Scientific Committee).

The conclusions that have been arrived at are not at present put forward for universal adoption, but are stated with the request that you will be so good as to give them your careful consideration, and make any comment upon them.

The following methods have been suggested for the formation of the generic name of multigeneric orchid hybrids:

1. That the name consist of parts of the names of the genera which enter into the composition of the hybrid—the system at present in use (see list appended).

   This method will lead to the formation of such unwieldy names as Dialaeliocattphronitis and Brassolaeliocattleysophroschomboepid i aleptotes.

2. That a consonant be chosen to represent each of the genera used in producing the hybrid as B for lælia, C for cattleya, D for sophronitis, and that these be followed by the vowel "a" when the genus is used once, "e" when it is used twice, and so on, as dabaca for sophronitis × læliocattleya, and Dabeca for sophrolælia × læliocattleya.

   It is thought that the names thus formed would not be euphonious or sufficiently distinct.

3. That one letter, preferably the initial letter, should be chosen to represent each genus used in hybridising: thus L for lælia, C for cattleya, S for sophronitis, and that these letters should be used to form the names of the resulting hybrids. Connecting vowels when necessary should be taken from the initial vowels, and the letter "y" should be used as a vowel sound between the components denoting the two sets of parents. Thus "lysoc" would denote the product of lælia × sophrocattleya.

   The names thus formed would seldom be euphonious, and the method of formation would not always prove sufficiently simple to grasp.

4. That the name of one of the genera entering into the composition of the hybrid be retained for it, as is the practice in naming natural hybrids in other groups of plants, e.g. in the Gramineae (see Rules of Nomenclature, Vienna Congress, 1905, Art. 32).

   The name would then lack distinctiveness.

5. That the name be a commemorative one with a conventional ending, such as "ara" or "orch," as Lawrenceara or Lawrenceorch.

   The former ending is considered the more euphonious.

6. That the name be a commemorative one with the syllable "hyb" prefixed to indicate the hybrid origin, as Hyblawrencea.

   While distinctive, the constant repetition of the syllable "hyb" would be likely to lead to confusion, and would be the reverse of euphonious.

The Sub-Committee consider that the suggestion No. 5 best fits the case, and are prepared to recommend the council that it be adopted as the method of coining names for multigeneric orchid hybrids, unless some more desirable method can be suggested.

The commemorative name chosen should be that of someone eminent as a student or as a grower of orchids, and the conventional termination "ara" should be used.

It is not proposed that this suggestion should interfere with the use of names already in existence or with the coining of names by combining parts of the names of the parent genera when two genera only are crossed.

The Sub-Committee further think it desirable that the combinations such as epidendrum × sophronitis already in existence should be written without a hyphen, as epiphronitis (see list).

They further suggest that if the specific name attached to a hybrid were of the Latin form, varietal names would be easier of addition, so that such forms as Læliocattleya "Phœbe" illustrissima might in the future be avoided.

Hoping to be favoured with your views at as early a date as convenient.

F. J. Chittenden,
Secretary of the Sub-Committee.
R.H.S., Vincent Square, S.W.

LIST OF INTERGENERIC HYBRIDS AT PRESENT IN EXISTENCE.

Group.	Parent Genera.	Hybrid
1.	Anguloa—Lycaste	Angulocaste
2.	Anaectochilus—Haemaria	Anaectomaria
	Dossinia—Haemaria	Dossinimaria
	Macodes—Haemaria	Macomaria
3.	Chondrorhyncha—Zygopetalum	Chrondropetalum
	Batemannia—Zygopetalum	Zygobatemannia
	Colax—Zygopetalum	Zygocolax
	Aganisia—Zygopetalum	Zygonisia
4.	Cochlioda—Odontoglossum	Odontioda
	Miltonia—Odontoglossum	Odontonia
5.	Calanthe—Phaius	Phaiocalanthe
	Cymbidium—Phaius	Phaiocymbidium
6.	Brassavola—Cattleya	Brassocattleya
	Brassavola—Epidendrum	Brassoepidendrum
	Brassavola—Lælia	Brassolælia
	Diacrium—Cattleya	Diacattleya
	Diacrium—Lælia	Dialaelia
	Cattleya—Epidendrum	Epicattleya
	Diacrium—Epidendrum	Epidiacrium
	Lælia—Epidendrum	Epilaelia
	Sophronitis—Epidendrum	Epiphronitis
	Lælia—Cattleya	Laeliocattleya
	Lælia—Leptotes	Leptolaelia
	Schomburgkia—Cattleya	Schombocattleya
	Sophronitis—Cattleya	Sophrocattleya
	Sophronitis—Lælia	Sophrolaelia
	Tri-generic Hybrids.	
5.	Brassavola—Cattleya—Lælia	Brassocattlaelia
	Sophronitis—Cattleya—Lælia	Sophrolaeliocattleya
	Quadri-generic Hybrids.	
6.	Sophronitis—Brassavola—Cattleya—lælia	Not yet bloomed or named.

It is confidently expected that the whole of the genera in any one of the groups mentioned above will in the near future be combined together by hybridising—hence the need for a definite system of nomenclature for these hybrids.

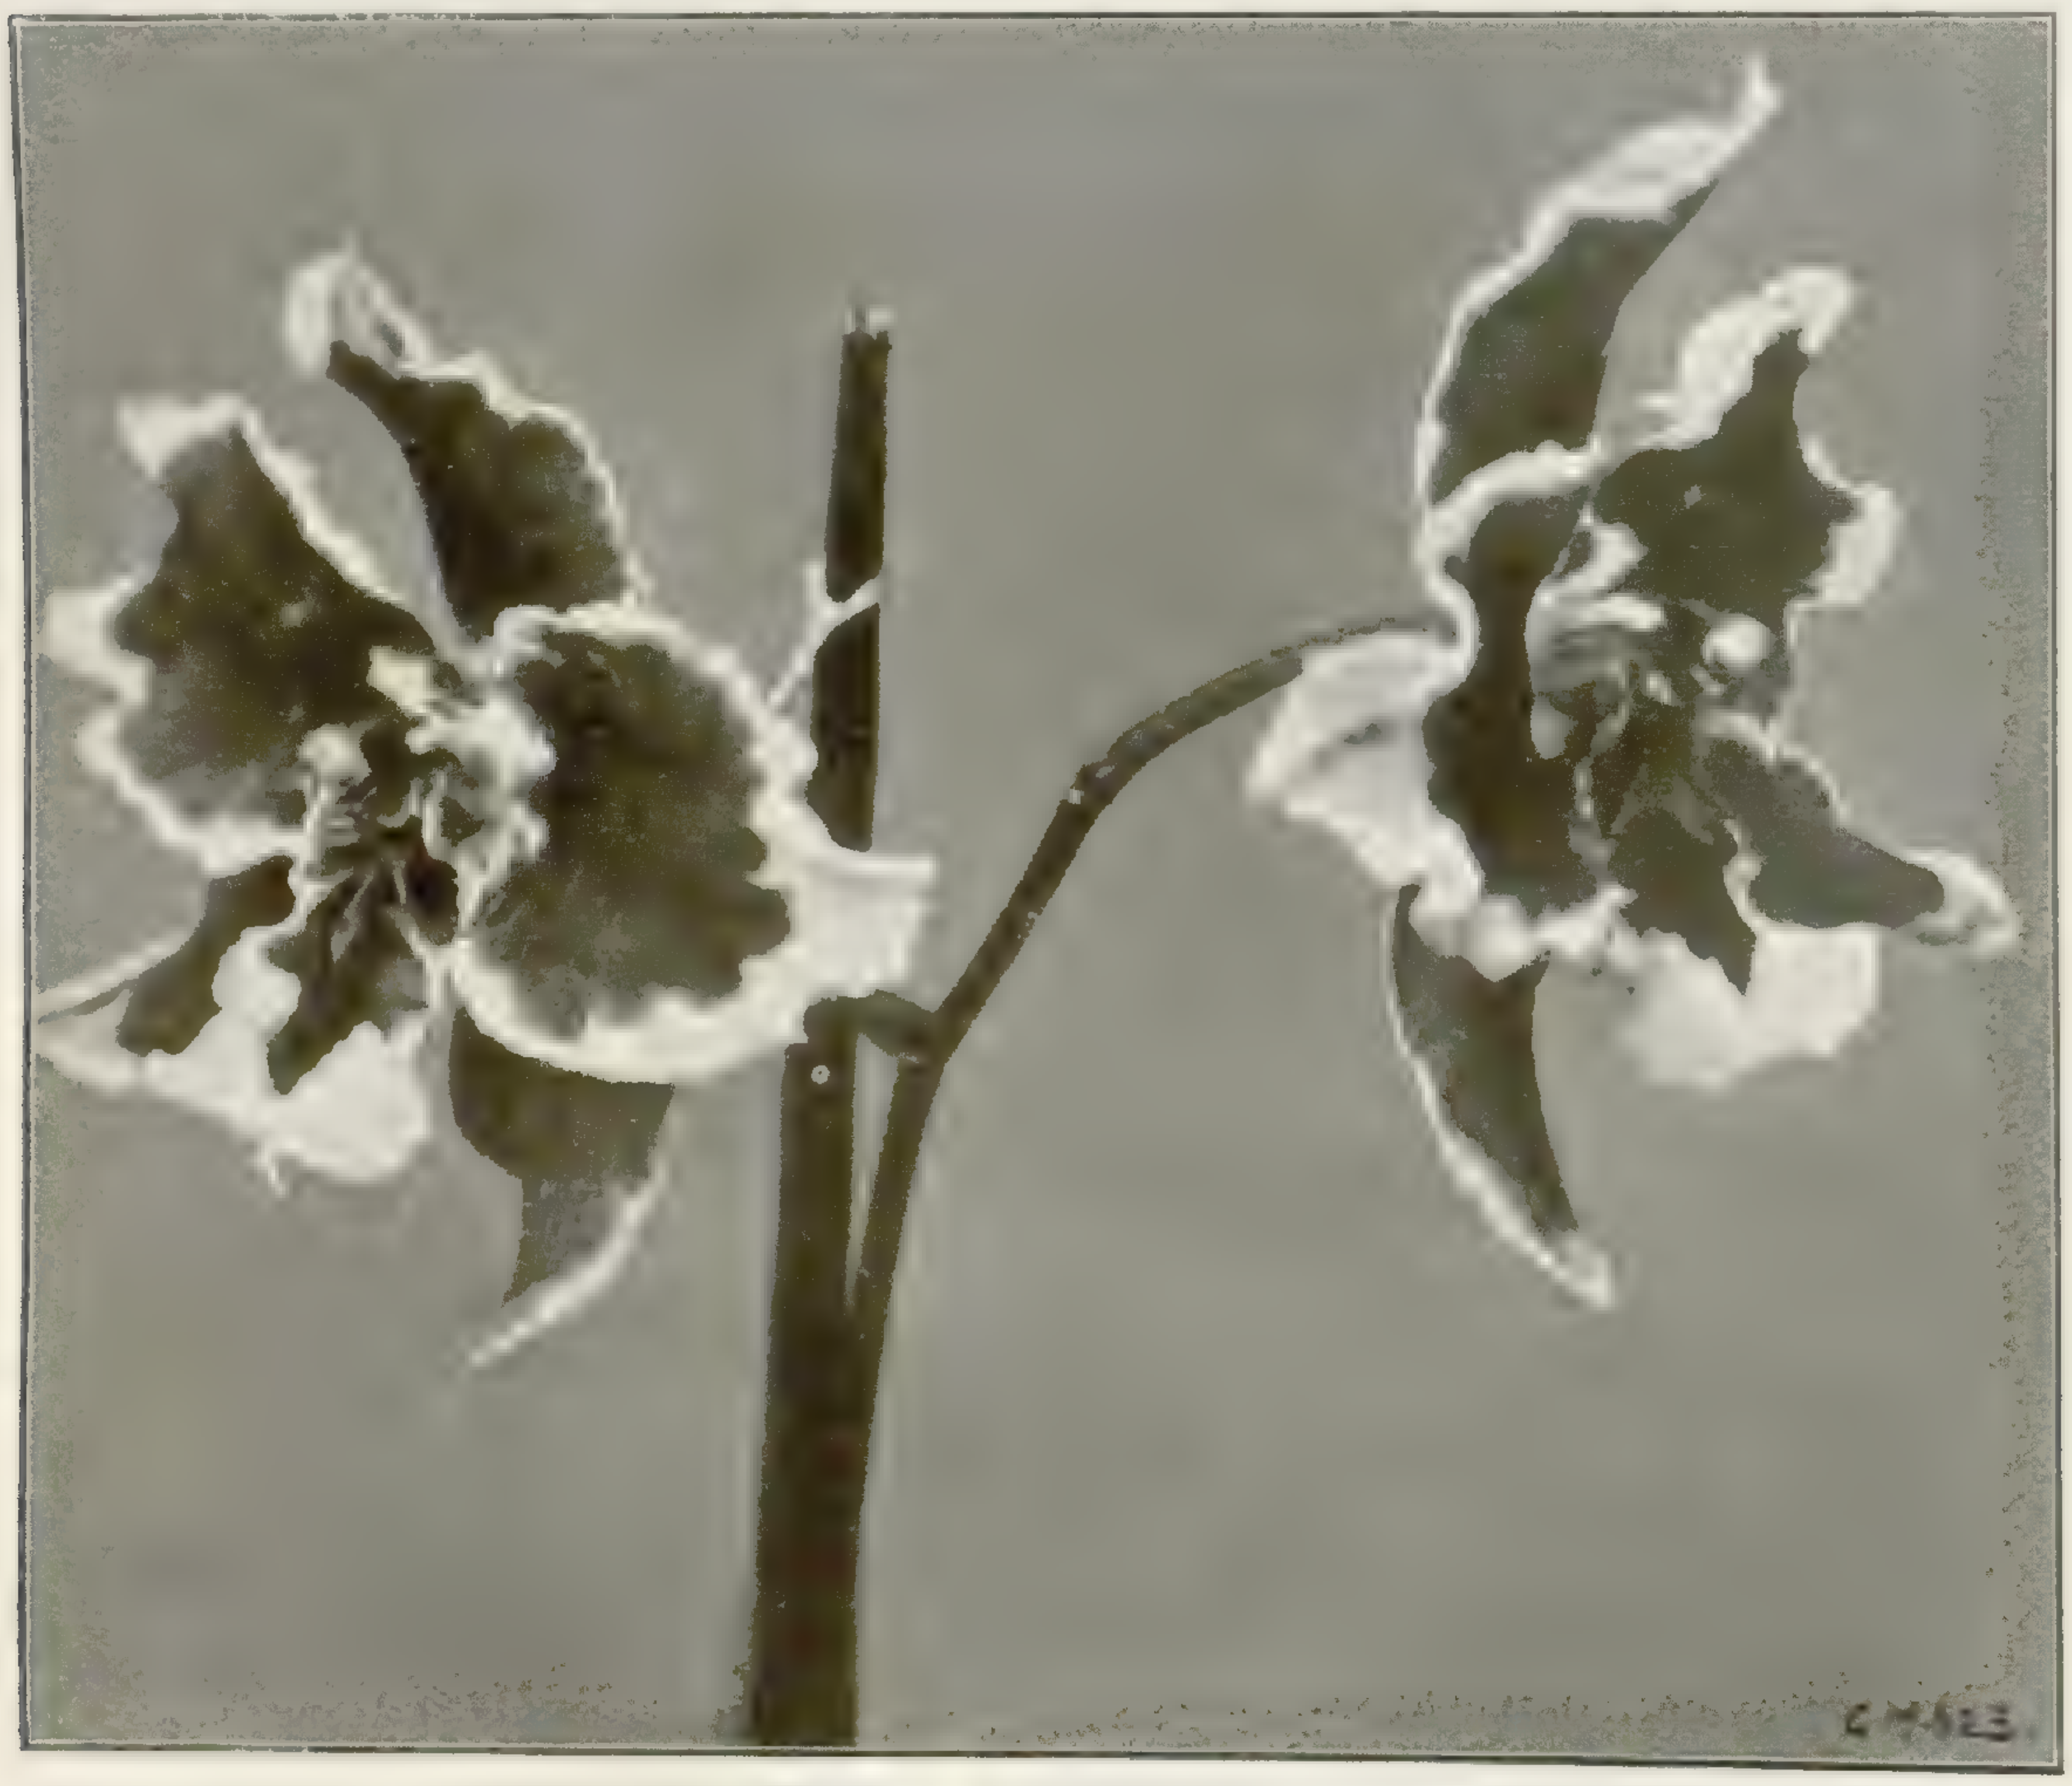
HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

Royal Horticultural Society.

As February 9 was the date of the annual meeting, exhibitors took full advantage of the opportunity of displaying their goods before the larger attendance this meeting always causes. There was a fine exhibition, and orchids, primulas, apples, and forced shrubs were the leading features.



ODONTOGLOSSUM ARDENTISSIMUM PHŒBE.

A beautiful variety, exhibited by Mr. Norman C. Cookson at the R.H.S. Meeting on the 9th inst., when a first-class certificate was conferred upon it. The colour is bright rose with white margin.

FLORAL COMMITTEE.

A beautiful exhibit was made right along the end of the hall by Mr. W. H. Page, Tangley Nurseries, Hampton. This was a grand display for the time of the year, and was altogether a magnificent effort. There were grand stands of Lilium speciosum rubrum, L. speciosum, and L. longiflorum, as well as groups of flowering plants of these fine lilies. Beautiful perpetual carnations, batches of the pink Queen Alexandra spiræas, and Golden Spur daffodils completed this very attractive contribution. Messrs. James Veitch and Sons, Chelsea, contributed a bright and interesting display of flowers, showing batches of Azalea amœna Hexe, lily of the valley, Kalanchoe Dyeri, Eupatorium vernale, and various Indian azaleas.

Messrs. Sutton and Sons' primulas were a great attraction, their neat habit and finely-formed flowers showing the results of long-continued, careful cross-fertilisation and selection. The whole display represented the firm's Giant Mixed strain. Early flowers were prettily shown by Messrs. Barr and Sons, Covent Garden, who had among other things, batches of snowdrops, lachenalias, yellow freesias, daffodils, crocuses, Iris reticulata, St. Brigid anemones, and Hamamelis arborea.

Messrs. Joseph Cheal and Sons, Crawley, sent alpine shrubs, hardy primulas, irises, daphnes, etc. Mr. W. A. Cook, gardener to Sir Edmund Loder, Bart., Leonardslee, Horsham, showed several fine examples of Sarracenia purpurea, lifted from the open ground. Perpetual carnations in great variety were exhibited by Messrs. Hugh Low and Co., who had Rival, Defiance, Britannia, Mrs. H. Burnett, and Black Chief in fine condition. Some fine Chinese primulas, representing an excellent large-flowered strain, were exhibited by Messrs. H. Cannell and Sons, Swanley. Mrs. Jean Ward—a very beautiful and distinct new rosy pink double variety, Mr. John Ward, Mrs. C. F. Raphael, Mr. J. A. Gardiner, and Moonlight—a pure white, were extra fine. Messrs. R. Wallace and Co., Colchester, showed the pretty little Cyclamen Coum in variety, a charming lot of crocuses, and irises and snowdrops. Mr. Herbert Chapman, Rye, again showed Freesia Chapmani and numerous freesia seedlings.

A large-flowered strain of Primula obconica, shown largely by Messrs. T. S. Ware, Lim., Feltham, made a fine show, with P. floribunda and P. Isabellina. Messrs. G. and A. Clarke, Dover, arranged a rock garden, and filled it with primulas, alpine shrubs, daffodils, and succulents, etc., and they had Veltheimia capensis, the latter a fine form of V. viridiflora. A splendid strain of cyclamens, staged by Mr. W. Seward, The Beeches, Hanwell, was greatly admired; the flowers were of fine size, and great purity of colour, and the plants finely flowered. Mr. George Mount, Canterbury, made a small but exceedingly beautiful exhibit of Mrs. W. J. Grant, Richmond, and Joseph Lowe roses—delightful blooms. Messrs. Robert Sydenham, Lim., Birmingham, showed good lily of the valley, grown in fibre. Mr. L. R. Russell, Richmond, made a pretty exhibit of Hamamelis arborea.

Exquisitely beautiful was the fine display of forced flowering shrubs, beautifully arranged by Messrs. R. and G. Cuthbert, Southgate, Middlesex. Prunus triloba, standards and bushes of Azalea mollis, in great variety of colours, Staphylea colchica, Lilac Marie Legraye, Forsythia suspensa, Magnolia conspicua, and M. Soulangeana, Pyrus atrosanguinea, and wistarias, were the subjects chiefly employed, with, of course, an ample setting of palms, ferns, etc.

Messrs. Wm. Cutbush and Son, Highgate, contributed a charming bank of forced flowering shrubs and early hardy flowers, and a beautiful exhibit of perpetual carnations, including numerous novelties. Mr. G. Reuthe, Keston, Kent, showed camellias, snowflakes, hardy heaths, saxifragas, crocuses, and other interesting subjects. Mr. H. Burnett was well represented by a very fine group of beautiful blooms of perpetual carnations. Messrs. H. B. May and Sons, Edmonton, contributed ferns in variety, and batches of cyclamen, Primula obconica, etc. Polypodium crassinervum was a conspicuous plant in the group.

ORCHID COMMITTEE.

A wonderful, brilliant, and extensive exhibit of orchids was charmingly arranged by Messrs. Charlesworth and Co., Haywards Heath, Sussex. This firm has set up many fine displays of orchids, but we doubt whether any previous effort has been quite as beautiful as this. One side of a long table was filled with these interesting and beautiful plants, all flowered delightfully. The centre was filled with a magnificent lot of Phalænopsis Schilleriana, in rude health, and carrying splendid spikes of exquisite blooms; altogether there were about a hundred plants of P. Schilleriana, some carrying two spikes. P. Stuartiana was also represented, and there was a rare plant of P. Schilleriana alba. At either end were groups of other orchids, odontoglossums forming the chief feature of one group, and cattleyas and lælio-cattleyas the other group. Among the odontoglossums there were very fine examples of O. Lambeaeanum, O. Armain villiersense, O. Harryano-crispum, O. Rolfæ, and O. crispum in variety.

Messrs. Cypher and Sons, Cheltenham, contributed a very pretty display of orchids, and as usual, they staged a very interesting lot of cypripediums, that included C. Hitchense, C. aureum Hyeanum, C. Swinburnei magnificum, and C. Mrs. W. Mostyn. They also had Phaio-cymbidium Chardwarense, Angræcum eburneum, and several very pretty odontoglossums. In Messrs. Hugh Low and Co.'s display of orchids the special features were Cymbidium Wiganianum with five spikes, Lælio-cattleya Charlesworthi, Dendrobium nobile virginale, Dendrochilum glumaceum and a useful selection of cypripediums.

Messrs. Moore, Lim., Rawdon, Leeds, brought up a little group of orchids, in which Cypripedium Rothschildeanum Dulcote var. with a three-flowered spike, was conspicuously good. There were also C. Chapmani, C. Mrs. Francis Wellesley, C. aureum Hyeanum, C. Maudiæ, and several odontoglossums and dendrobiums.

Mr. Mertens, Mont St. Amand, Belgium, brought over several delightful odontoglossums, notably O. laudatum, O. Wilcheanum, O. eximium, O. Vuylstekei, and several hybrids. A collection of hybrid cypripediums was shown by Messrs. James Veitch and Sons to show the great variation from one cross, the cross in this case being C. villosum and C. Euryades; some of the seedlings were very good, and some very poor, while the variation in colouring was remarkable. The same firm showed odontoglossums, Lycaste Skinneri and Lælia Nemesis, the latter a cross between L. anceps and L. superbiens.

The elegant Lælia anceps was finely shown by Messrs. J. and A. A. McBean, Cooksbridge, Sussex, who exhibited white varieties exclusively, and in fine style. Mr. H. Alexander, orchid grower to Lieut.-Colonel Holford, Westonbirt, Gloucester, brought up several beautiful orchids, and the chief of these were Lælio-cattleya Goldfinch superba (A.M.), Cymbidium Holfordianum, Cypripedium Helen II. Holford's var. He also had a magnificent specimen of Odontoglossum crispo-Harryanum, carrying 125 flowers on [illegible] spikes, one spike having 65 flowers; a Lindley medal was unanimously awarded for this example of cultural skill.

Mr. H. J. Chapman, gardener to Norman C. Cookson, Esq., Oakwood, Wylam-on-Tyne, [illegible] up a group of very choice orchids. [illegible] were Cypripedium Chapmani, C. Mrs. [illegible] Drewitt's var., C. Orion bellum, C. [illegible] C. Wm. Lloyd superbum, C. triumphans [illegible] perbum, Odontoglossum crispum [illegible] O. Lindeni, O. ardentissimum Phœbe [illegible]

Mr. Collier, gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate, showed a little group of botanical orchids, such as Restrepia striata, Dendrobium æmulum, Masdevallia cuculata, M. Chimæra, Dendrobium Veitchi, and Phaio-calanthe Colmani. Mr. Thwaites, Chessington, Streatham, exhibited Odontioda Bradshawæ Chessington var. Mr. J. Forster Alcock, Exhims, showed Cypripedium Leander Exhim's var. (A.M.), a very neat flower.

FRUIT AND VEGETABLE COMMITTEE.

Very fine were the apples so effectively displayed by Messrs. G. Bunyard and Co., Maidstone. The firm had large dishes and baskets of fruit, representing one hundred and sixty varieties. Red Winter Reinette, King of Tomkin's County, Rosemary Russet, Newton Wonder, Alfriston, Lane's Prince Albert, Lord Derby, Malster, and Lady Henniker were apples particularly well represented by the Maidstone firm.

A handsome display of well-grown potatoes was made by Messrs. James Carter and Co., High Holborn. The tubers, all beautifully clean, and of fine form, were pleasingly arranged, and we may note Longkeeper, Record, Snowball, Early Favourite, Superlative, Leinster Prolific, First Crop, Goodfellow, Lilywhite, Canon, and Gold Mine, as being especially good among one hundred and seventy-five varieties. Mr. C. Foster, Horticultural Department, University College, Reading, exhibited forced Linnæus rhubarb, asparagus roots, from one to five years of age from seed, Witloof chicory, forced seakale, Sutton's Early Paris frame lettuce, and Sutton's Eclipse tomatoes.

Mr. Waghorn, Maidstone, showed the "Very Quick" potato planter, a tool something like a double trowel with long handles; a hole is made with it, and the seed set dropped into the hole while the tool is in position, and then the planter is withdrawn, allowing the soil to fall loosely over the potato.

CERTIFICATES AND AWARDS.

First-Class Certificate. — For Odontoglossum ardentissimum Phœbe, from N. C. Cookson, Esq. (gardener, Mr. H. J. Chapman), Oakwood, Wylam-on-Tyne.

Award of Merit.—To Cypripedium Leander, Exhim's var., for Mr. J. Forster Alcock, Exhims. To Lælio-cattleya Goldfinch superba, from Lieut.-Colonel Holford (orchid grower, Mr. H. G. Alexander), Westonbirt, Gloucester.

MEDALS.

Gold.—Mr. W. H. Page, Tangley Nursery, Hampton, for liliums and carnations. Messrs. G. Bunyard and Co., Maidstone, for apples. Messrs. Charlesworth and Co., Haywards Heath, for orchids.

Silver-Gilt Flora.—Messrs. R. and G. Cuthbert, Southgate, for forced shrubs. Mr. Norman C. Cookson, Oakwood, Wylam-on-Tyne, for orchids.

Silver-Gilt Banksian.—Messrs. W. Cutbush and Son, Highgate, for carnations and forced shrubs. Mr. W. Seward, Hanwell, for cyclamens. Messrs. James Veitch and Sons, Chelsea, for flowering plants.

Silver Flora.—Messrs. J. and A. McBean, Cooksbridge, for orchids. Messrs. Hugh Low and Co., Bush Hill Park, Enfield, for orchids. Messrs. Moore, Lim., Rawdon, Leeds, for orchids. Mr. H. Burnett, Guernsey, for carnations. Messrs. Henry Cannell and Sons, Swanley, for primulas. Messrs. Sutton and Sons, Reading, for primulas.

Silver Banksian.—Messrs. G. and A. Clarke, Dover, for rockwork exhibit. Messrs. Hugh Low and Co., Enfield, for carnations, etc. Messrs. H. B. May and Sons, Edmonton, for ferns and flowering plants. Mr. George Mount, Canterbury, for cut roses. Messrs. J. Peed and Son, West Norwood, for alpines and daffodils. Mr. L. R. Russell, Richmond, for flowering shrubs. Messrs. Thos. S. Ware, Lim., Feltham, for primulas, etc. Messrs. Jas. Veitch and Sons, Chelsea, for orchids. Mr. C. Foster, University College, Reading, for forced seakale, rhubarb, and salads.

Silver Knightian Medal. — Messrs. James Carter and Co., High Holborn, for collection of potatoes.

Silver Lindley Medal.—Mr. H. G. Alexander, orchid grower to Lieut.-Colonel Holford, Westonbirt, Gloucester, for a fine specimen of Odontoglossum crispo-Harryanum.

ANNUAL MEETING.

There was a moderate attendance in the Lecture Hall at three p.m., when Sir Trevor Lawrence, president, opened the annual meeting proceedings. After the usual formalities, the President rose to propose the adoption of the report and balance-sheet. He referred to the chief points in the report, largely as we gave them on p. 100. He expressed the thanks of the council to Mr. F. J. Chittenden for the admirable work done in connection with the laboratory and journal, and eulogised the services of the Rev. W. Wilks and the office staff, and Mr. S. T. Wright, Mr. A. Smith, and the Wisley staff. The President then presented the Rev. W. Wilks and Mr. Wm. Marshall, V.M.H., with the Veitchian medal, and Sir Jeremiah Colman, Bart., and Mr. Charles Ross with the Victoria Medal of Honour in Horticulture. Sir J. Colman and Mr. C. Ross both acknowledged the receipt of this honour, and, in an admirable speech, the Rev. W. Wilks, in responding for Mr. Marshall and himself, showed what manner of man Mr. James Veitch was, and how he had raised the whole horticultural profession. This résumé of the life and character of Mr. James Veitch gave the fellows present some idea of the kind of man in whose memory and honour the Veitchian medal was struck.

Mr. J. Gurney Fowler seconded the adoption of the report and balance-sheet, and entered into a few financial details.

Mr. H. J. Elwes expressed regret that the report contained no reference to the library, and that the financial statement showed only £29 had been spent on the library, and he wished for a definition of the society's relations with the Lindley trustees. He had endeavoured to persuade the council that early volumes of the Gardeners' Magazine should be placed in the library, as they contained valuable information, not obtainable elsewhere, but he was informed that it was not considered necessary to add these volumes. He would like to see more money spent on books, and a committee appointed to make a selection of desirable additions.

The Rev. J. Jacob endorsed Mr. Elwes' remarks, and suggested £1,000 should be at once set aside for the purchase of old books dealing with floricultural matters, and he also thought a committee should be appointed to select the books that were deemed most necessary, and that books purchased by the society should be marked so as to distinguish them from those belonging to the Lindley Trust.

Mr. J. McIndoe asked whether it was right for the society to send out its own paid officers as advisers and landscape gardeners, and thus reduce the opportunities of those Fellows already engaged professionally in such work.

Sir Trevor Lawrence briefly replied to the several questions raised, excepting Mr. McIndoe's, but the answers given were noncommittal and very indecisive. Mr. Elwes observed that up-keep and extension of the library should be considered as essential a part of the society's work as Wisley or the Temple show.

The motion was put, and carried, and the proceedings closed with a vote of thanks to the President.

Horticultural Club.

FEBRUARY 9.

The annual meeting and dinner of the Horticultural Club was held on Tuesday last, under the presidency of Mr. Harry J. Veitch, V.M.H., the chairman and treasurer of the club. A satisfactory report and financial statement was presented to the members assembled in annual meeting, and both were unanimously adopted. These showed that there had been an increase in membership and income, and that there was a substantial balance on the year's work. The lectures given at the monthly conversaziones had, the report stated, been of great excellence, and the attendance had been good. Owing to the multiplicity of functions in London last year the annual excursion had not taken place, but the committee hoped to arrange for one in the coming summer. The whole of the officers and members were re-elected, and Mr. White and Mr. C. E. Pearson were elected members of committee.

The dinner was exceptionally successful. About one hundred members and their friends sat down. The speeches were commendably short, and the musical entertainment, which was generously provided by Sir Frank Crisp, was of exceptional excellence. The usual loyal toasts having been submitted by the Chairman, and duly honoured.

Mr. George Paul, V.M.H., proposed the toast of "The Royal Horticultural Society," and, in doing so, referred to the splendid work that has been, and is being, done by the society. He thought, however, a larger proportion of the income should be spent in the furtherance of horticulture, as £7,000 was a large sum to invest in any one year. The Rev. Joseph Jacob acknowledged the toast in a humorous speech.

Mr. Veitch, in proposing "The Horticultural Club," expressed his regret that, owing to indisposition, Sir John Llewelyn, Bart., was unable to be present. He briefly referred to the usefulness of the club as a rallying point for horticulturists, and the importance of the lectures and discussions at the monthly meetings. Mr. H. Morgan Veitch acknowledged the toast, and in the course of his response referred to the desirability of legislative action with a view to placing nurserymen under similar conditions to market gardeners in the matter of compensation for improvements, notice, etc.

The other toasts were "The Chairman," proposed by Mr. E. White, and received with musical honours. "The Visitors," proposed

Eckford's
GIANT
SWEET PEAS

When growing Sweet Peas grow only the best.

A superb display occupies no more space, takes no more time to cultivate, neither does it cost any more than a poor show. To obtain the very best, send direct to Eckford for your seeds; **but remember they are only genuine when obtained direct from Wem.**

WE DO NOT SUPPLY THE TRADE.

1909 NOVELTIES.

Write for Catalogue containing full particulars of the special novelties for this season.

Special Novelty Offer.

One packet each of 8 grand novelties, 7/6, post free.

Villa (B) Collection.

24 splendid varieties, suitable for exhibition, fifty seeds of each, **5/6.**

Villa (C) Collection.

12 splendid varieties, suitable for exhibition, fifty seeds of each, **2/9.**

A Booklet giving full particulars on the Culture of Sweet Peas given with every order.

FREE.

Send a post-card for Coloured Illustrated and Full Descriptive Catalogue, it is sent post free. Write to-day.

HENRY ECKFORD, F.R.H.S.,
(Dept. 5), **Sweet Pea Specialist,**
WEM, Shrop.

by Mr. George Munro, V.M.H., and acknowledged by Mr. P. Anderson Grahame. In addition to the toasts on the programme, Mr. Bilney proposed the health of Sir Frank Crisp, the toast being accorded musical honours, and the Chairman submitted the health of Mr. E. T. Cook, the hon. secretary, and the toast was heartily received.

Beckenham Horticultural Society.

On Friday, the 29th ult., Mr. E. R. Seadon, of Bromley (bee expert with the late Mr. S. J. Baldwin), lectured before the above society on "Beekeeping and its Advantages," illustrating his remarks by lantern slides. Many of the views were to show the value of the bee from a horticultural point of view, i.e., the fertilisation of flowers. One of the slides showed an apple perfectly fertilised, as against one insufficiently fertilised. Another slide showed sections of the same fruits and of pears. Of course, samples of similar fruit would be forthcoming, apart from the bee. A hearty vote of thanks was accorded Mr. Seadon.

There was also placed on the platform, through the kindness of Mr. Leech, of Wood Hall Gardens, Dulwich, fine flowering branches of Hamamelis (Wych Hazel), in several varieties. These were cut in bud state, and placed in water in a stove for two or three days, and were in full beauty, and much admired.

Cardiff Gardeners' Association.

The fortnightly meeting of the above association took place at St. John's Schools, Mr. H. R. Farmer presiding. A lecture was given by Mr. M. Toy, foreman at Cardiff Castle Gardens, on "Perpetual-flowering Carnations and Malmaisons." Introducing his lecture, Mr. Toy pointed out the advantage of the "perpetual varieties" for all kinds of decorations, more especially in the arrangements of vases, on account of their long stems. In propagating great care should be taken to get the cuttings from clean, healthy plants, and insert them by the first week in January, placing them under hand-lights with a bottom heat of 55 degrees. Mr. Toy explained the necessary culture of these most popular flowers, including soils, early stopping, and watering, diseases, and pests. Much the same treatment was necessary for the Malmaisons, with the exception that Mr. Toy preferred the layers of these to the cuttings.

Mr. Wheeler opened the debate, which led to a heated discussion on Perpetual v. Tree Carnations. Mr. Malpass proposed, and Mr. Howe seconded a hearty vote of thanks to Mr. Toy for his excellent lecture, which was carried enthusiastically.

Chester Paxton Society.

In the course of a lecture given at the Grosvenor Museum, on Saturday, on "The Agriculture and Horticulture of Denmark," Mr. G. P. Miln gave some interesting statistics relating to the immense quantities of agricultural produce that are annually exported from Denmark. Owing largely to the co-operative movement assisting the smaller farmers and peasants of Denmark, the exports of butter, cheese, bacon, and eggs have, during the past twenty-six years, risen from about £3,000,000 sterling to over £16,000,000 sterling, the greater portion of this sum being paid by Great Britain. High-class quality and a uniform standard have been the aim of the Danes, and in this respect they have, by the aid of scientific methods, been highly successful. The lecturer also touched briefly upon other phases of Danish agriculture, including the various breeds of cattle, horses, and sheep, as well as the culture of cereals and other agricultural crops. Reference was also made to the attention which the Danish Government gives to forestry, one of the laws relating to this being that no proprietor is allowed to fell timber unless he plants a similar acreage with young trees.

Under the heading of horticulture, Mr. Miln also dealt with the culture of fruit in Denmark and gardening topics generally. The lecture, which was illustrated by a series of beautiful lantern slides, was greatly enjoyed by the audience, who showed their appreciation by according to the lecturer a very hearty vote of thanks.

OBITUARY.

◆

MR. GEORGE A. DICKSON, V.M.H.

We greatly regret to learn of the death of Mr. George A. Dickson, V.M.H., head of the firm of Dicksons, Lim., Chester. Death occurred at Springfield, Newton, Chester, on Saturday last. Mr. Dickson, who was seventy-four years of age, occupied such a high position in the world of horticulture that he was selected as one of the first sixty to receive the Victoria Medal of Honour in Horticulture. For a very long number of years, indeed ever since the amalgamation of the two Dickson firms into Dicksons', Lim., he was at the head of the business. He did not often come to London, but he always took a great interest in the work of the two great gardening charities, and on one occasion presided at a dinner following the annual meeting of the Gardeners' Royal Benevolent Institution. He took a great interest in civic matters, was Mayor of Chester in 1886, and received the Honorary Freedom of the City on the occasion of the Diamond Jubilee celebration.

TRADE NOTES.

In view of certain advertisements, it may be stated that the only three horticultural firms who received gold medals or higher awards at the hands of the International Jury (confirmed by the Governing Council) for permanent exhibits at the Franco-British Exhibition were Messrs. Kelway and Son, Langport, Messrs. Sutton and Sons, Reading, and Messrs. James Carter and Co., High Holborn, London, W.C., vide the authorised list issued by the Council of the Franco-British Exhibition, published in the GARDENERS' MAGAZINE.

We are reminded that there is still time to spray fruit trees for the purpose of cleansing them from moss, lichen, and the many insect pests that harbour therein, and that do so much harm to the crops at a later date. The reminder comes in the form of a pamphlet from Messrs. Wm. Cooper and Nephews, Berkhamsted, referring to their V Fluids for spraying fruit trees. From the many testimonials received, it is evident that the V1 Fluid is very useful for present spraying, and that V2 Fluid is admirable for dealing with insect pests that appear in summer and prey upon the foliage, while yet another fluid, distinguished as V2 K, is useful for destroying mildew.

From Messrs. Wm. Artindale and Son, Norfolk Market Hall, Sheffield, we have received a gathering of Primula obconica gigantea. This is a remarkably fine strain, the large richly-coloured flowers being borne in large heads on long stiff stems. We are informed that the plants from which these flowers were gathered have been continuously in bloom since last September. They have not been grown in any special mixture, while a temperature of about 50 deg. has been maintained for them. Unquestionably a fine strain of P. obconica such as this provides one of the most useful of winter-flowering plants.

DESTRUCTION OF VERMIN. — Most gardens are pestered with Rats and Mice. Every effort should be made at this time of the year to exterminate them before seeds are sown. Danysz Virus is first rate stuff for killing these vermin. Single tube, 2s.; three tubes, 5s. Post free from DANYSZ VIRUS LTD., 52, Leadenhall Street, Garden Dept., London, E.C.-[Advt.]

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

MANURING SHRUBBERY BORDER.—M. C. D., Surbiton: The old decrepit shrubs should be at once lifted and burned, and the sites they occupied be deeply dug, adding some old crumbly manure as the work proceeds. Fork in similar manure around the plants that remain, or, better still, remove the soil down to the roots, and in its place put some good new soil. Why not obtain a guelder rose, a philadelphus, a lilac, and a flowering cherry to take the places of the shrubs removed? They would brighten up the borders beautifully. Plant at once, and see that the borders are supplied with water in spring and early summer if the weather is at all dry.

FAILURE WITH TULIPS IN POTS.—J. N., Llandudno: It would have helped us considerably in arriving at a proper conclusion if you had sent us several of the bulbs. Sometimes fairly large bulbs are produced by high feeding, but they lack the firmness and ripeness essential for the production of first-class flowers, and, moreover, these are often young bulbs that are not likely to flower well under any conditions, and are certain to be failures when forced. It sometimes happens that there is a great run on certain varieties, and towards the end of the bulb season second-sized bulbs have to be used to fill orders, whereas if not sold, they would be replanted to produce stronger ones for sale the following year. So far as we can gather from your letter, the methods of cultivation followed should have produced better results had the bulbs been sound and ripe. We recommend you to place your orders early in the autumn, and with a firm of some reputation. It is a mistake to purchase bulbs at retail prices from the Dutch wholesale houses, because this can only be done after the trade has been supplied, and except in the cases of varieties that have become unpopular the bulbs are not of [illegible] flowering size. The best Dutch firms do not sell retail.

INSECTS ON ALPINE PLANTS.—D. C. H., Ledbury: It was not possible to identify the insects as they were mere fragments when received. As they appear to have been very tiny ones, it is difficult to imagine them capable of the mischief you ascribe to them. Lay traps of greased paper, or greased slates around the plants that are attacked, spreading the grease thickly, so that these jumping insects, alighting on it, will be unable to get away. You will soon be able to discover whether the insects are responsible for the damage, and a little patience and perseverance in trapping will soon account for, or at any rate materially reduce, the infestation.

VEGETABLE MARROWS.—S. E. B., Lincoln: To be a real success marrows should be started early, kept growing freely [illegible] planted out, and afterwards be given [illegible] material to grow in, and ample supplies of clear water and liquid manure. [illegible] seeds in early April, in pots, and place [illegible] in a warm frame or house to germinate. [illegible] the seedlings singly in three-inch pots as soon as they show their rough leaves, [illegible] when these pots are well filled with roots [illegible] the plants a shift into six-inch pots, [illegible] them rich substantial soil. Keep them [illegible] frame, and ventilate freely during

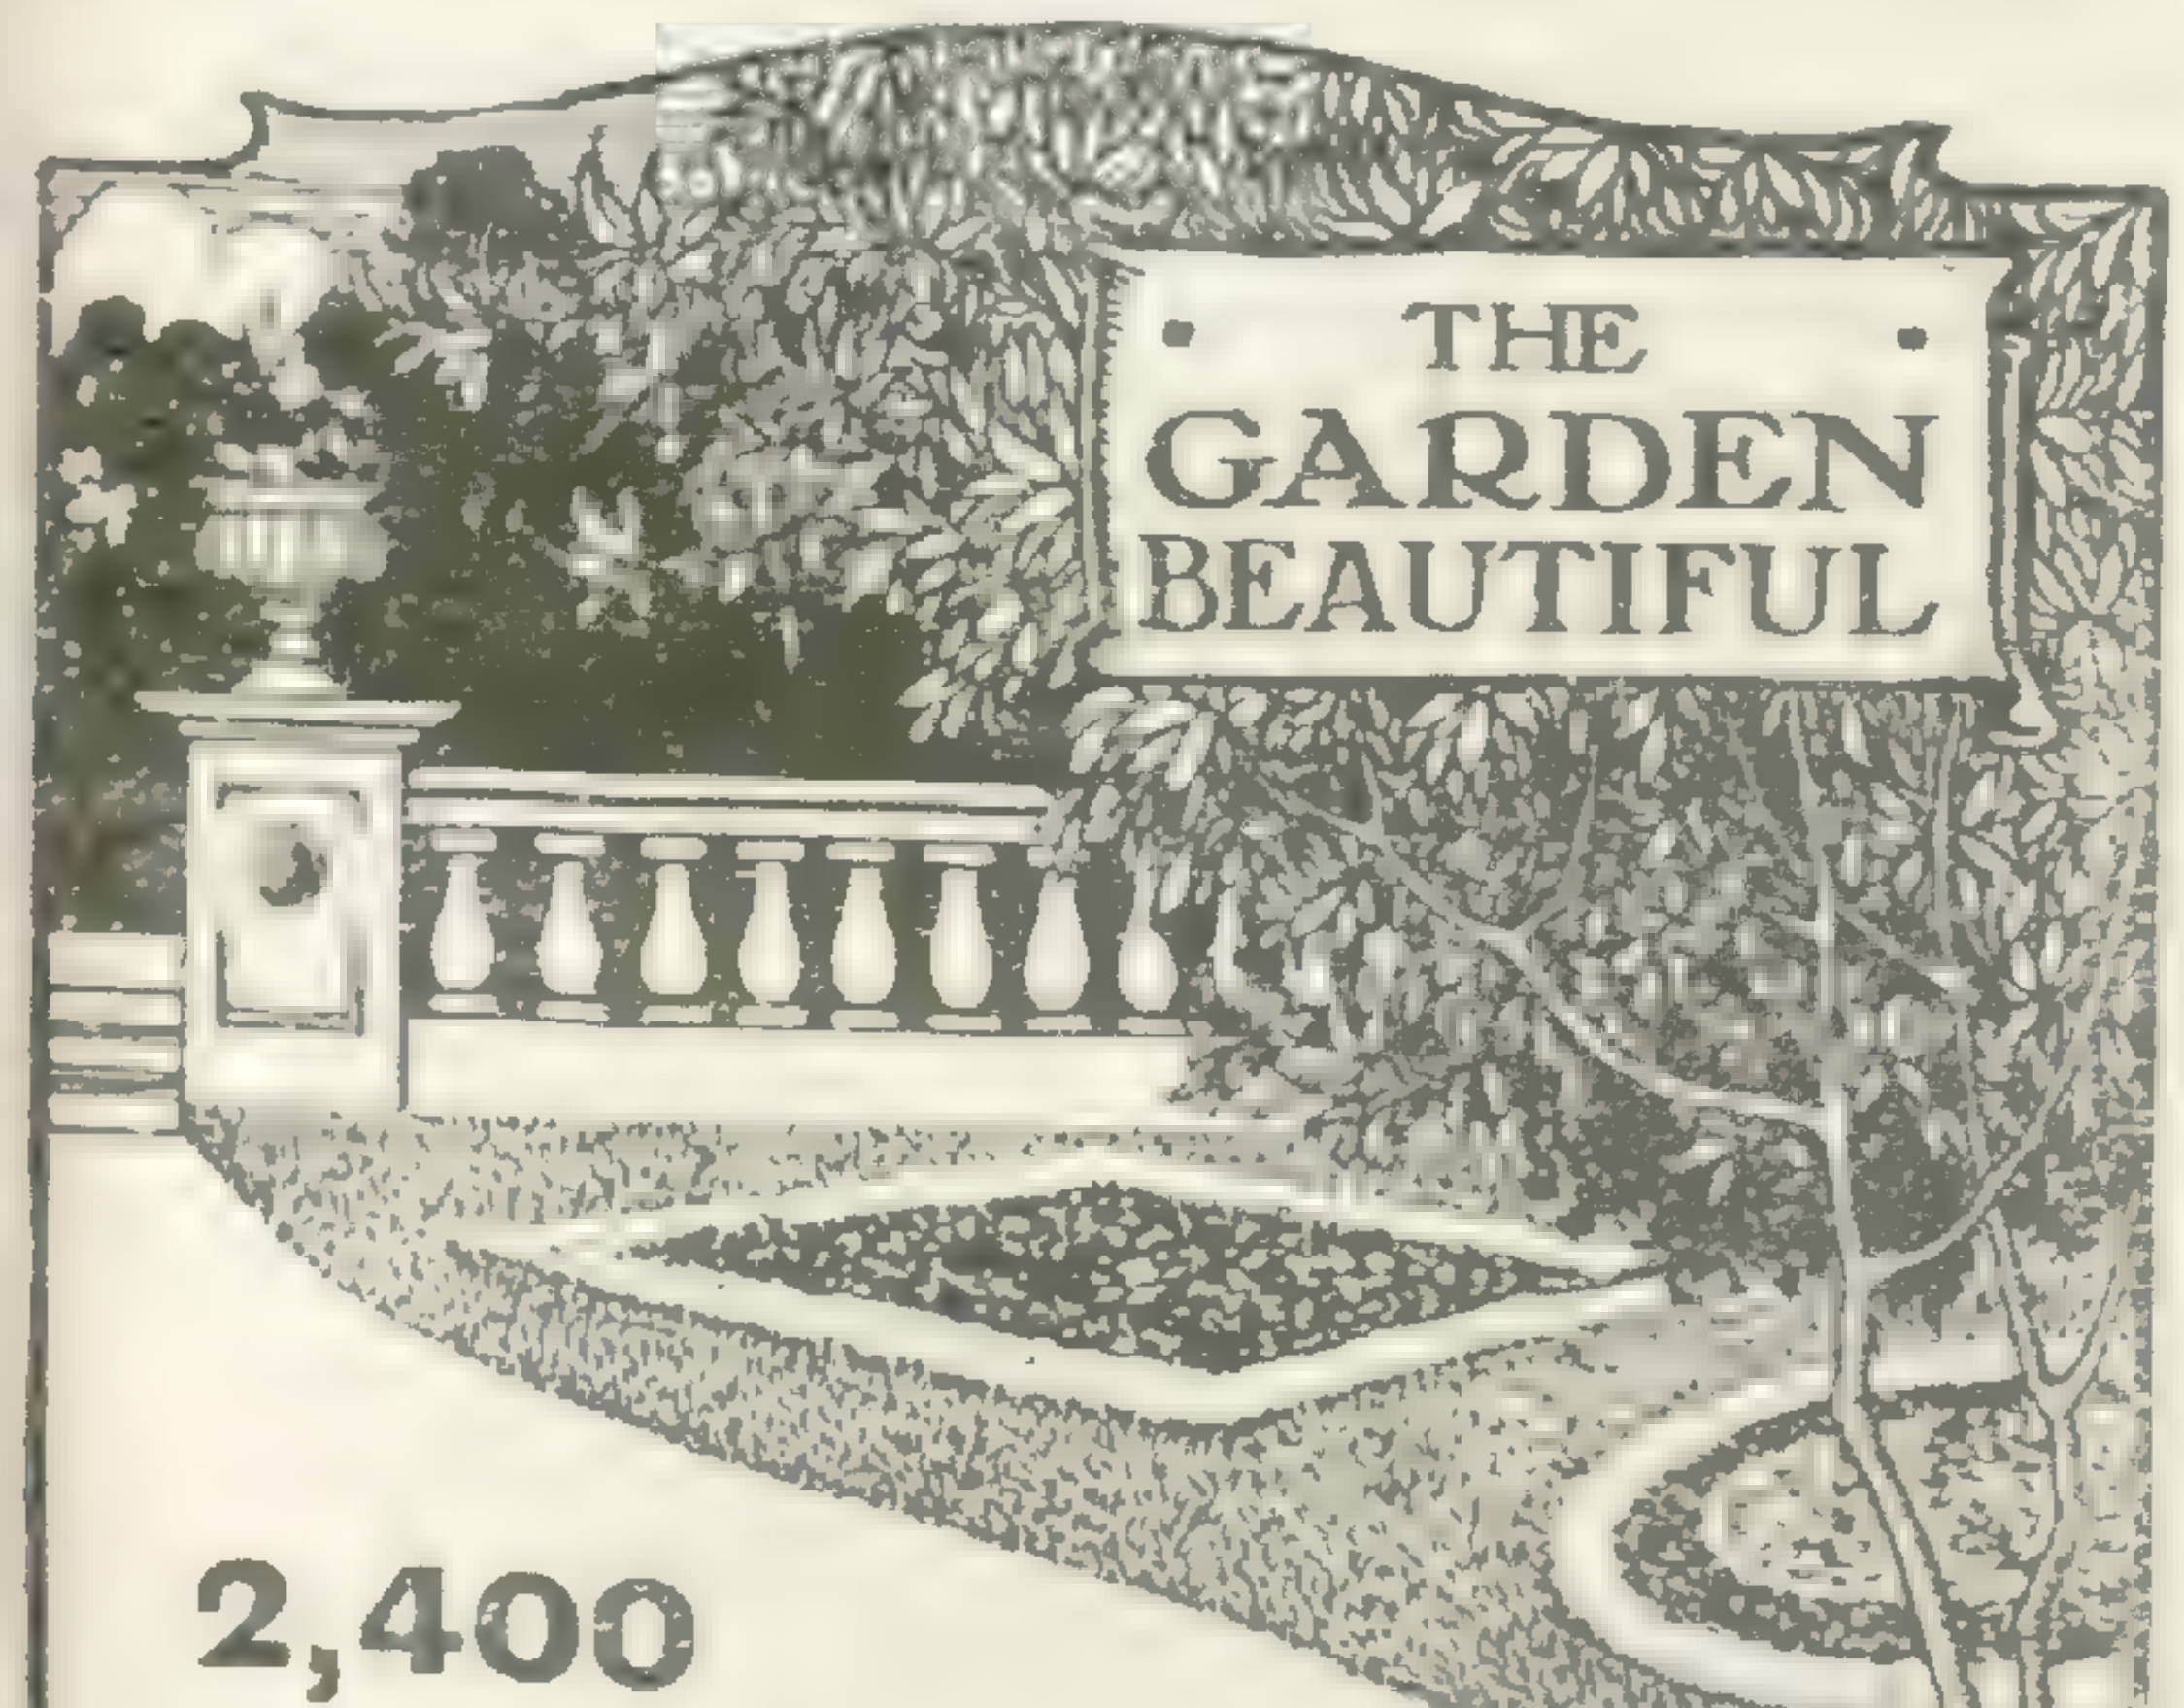
NOVELTY OF THE SEASON.
"PROGRESS,"
NEW PERPETUAL FLOWERING PINK.

It is quite distinct from any other pink; flowers a lovely rosy-mauve, of perfect form and calyx, borne on long, stiff stems, and with delightful fragrance; a grand border flower; also excellent for pot culture. Price 3s. each, or 5s. per pair.

C. H. HERBERT, The Nurseries, Hazelwood Road, Acock's Green, Birmingham.



2,400
"HAWLMARK"
SWEET PEAS, 3/-

Mr. T. INGLEBY, Morton, writes: "Your Lord Roberts Tomato has done the best of any I have had for cropping, quality, and firmness. I have cut as many as 14 to 20 from a bunch."

JOHN K. KING & SONS'
LORD ROBERTS TOMATO.

Remarkable for its cropping properties and unrivalled quality, bears fruit in huge clusters; fruit perfectly smooth, of a rich crimson colour, flesh wonderfully solid, and most delicious flavour.

Price 1/, 1/6 and 2/6 per packet.

OFFICES: 148 and 149, ALDERSGATE STREET, LONDON.

weather, increasing the ventilation so that by the end of May the marrows will be hardened sufficiently to be planted out where they are to fruit. In many cases marrows are not started early enough, and in other instances lack of success results from starving the plants during the seedling stage. Long Green, Long White, and Pen-y-byd are all fine varieties.

LILIES IN POTS.—L., Dulwich: Turn the bulbs out of the pots, remove all old soil from them, and clear away the decayed roots, flower stems, and damaged scales. Then repot in good loam and sand, and place the bulb so that the apex is little more than halfway up the depth of the pot; just cover the bulb, and thus leave plenty of room above for top-dressing when the stems arise, as these latter produce roots as well as the bulbs themselves. We had an idea we answered a similar question from you not long since.

SPRAYING PUMP AND INSECTICIDES.—G. B., Dublin: The best form of knapsack pump for spraying crops is the Vermorel type. There are now several of these on the market, and you should obtain particulars of each before deciding to purchase. Some seedsmen and sundriesmen keep several varieties in stock, so that they can be examined by intending purchasers. Write to the several makers and insecticide specialists that advertise in our columns for prices and particulars. We do not specially recommend any one nicotine emulsion; indeed we do not recommend specialities in this column, as it would be unjust to advertisers. All the emulsions are useful if used according to instructions. You can use a nicotine spray for bud protection until the bud scales begin to open.

NAMES OF PLANTS.

G. B., Dublin.—Erica carnea; flowering at the right time.

M. G., Chesterfield.—1, Adiantum Weigandi; 2, Helxine Solieroli; 3, Odontoglossum crispum.

T. G. P., Hunstanton. — 1, Sophronitis grandiflora; 2, Carex brunnea; 3, Hamamelis arborea; 4, Asparagus deflexus.

Seeds to Sow.—The work of seed-sowing under glass will now begin in earnest, and the first attention bestowed must be upon those requiring a long growing season; these include begonias, coleus, gloxinias, streptocarpus, etc., and, as all have very small seeds, only the lightest covering, if any, of soil should be given. Hard-coated seeds like those of cannas, many palms, and some acacias, are materially assisted in germination by having the outer seed-coat filed through before sowing. The seed of Musa (bananas), such as M. ensete, M. religosa, etc., which are employed for sub-tropical beds in summer, should be allowed to soak in tepid water 48 hours previous to sowing, and after sowing be placed over a brisk bottom heat. Varieties of solanum grown for their ornamental foliage, may be sown at the present time, to secure good strong plants in June, but it is well to delay sowing seed of the ricinus, hemps, and variegated maize, and similar fast-growing subjects, until March is well in. Antirrhinums may be sown where an early display is required, and carnations of the Margaret type will also call for attention at this date. Iceland poppies and gaillardias are often bad perennials in some gardens, fortunately they can be treated as annuals, from which we may expect a good return. Verbena venosa and tufted pansies may also be so treated, while the dwarf form of Salvia splendens must not be overlooked. Meconopsis seed, held over from autumn, must be sown as early as possible, as the seed of this family rarely retains its germinating power for any length of time. — Thomas Smith, Walmsgate.

HARDY FLOWERS are always popular, as they make the garden bright and attractive, and require but little attention. All the information required for their successful culture is given in Easily Grown Hardy Perennials, by G. H. Ves. Price 5s. net, by post in box, 5s. 6d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

FORTHCOMING ENGAGEMENTS.

WEDNESDAY, February 17.—Royal Meteorological Society Meeting.

THURSDAY, February 18.—Linnean Society Meeting.

TUESDAY, February 23.—Royal Horticultural Society: Fruit, Floral, and Orchid Committees meet at 12 o'clock; Lecture at 3 o'clock on "A Camping Tour through Syria to Petra in Arabia," by Mr. A. W. Sutton, V.M.H.; Scientific Committee at 4 o'clock.

TUESDAY, March 2.—National Amateur Gardeners' Association: Lecture on "Garden Dahlias," by Mr. George Gordon, V.M.H., 7.30 p.m.

THURSDAY, March 4.—Linnean Society Meeting.

SATURDAY, March 6.—French Horticultural Society of London.

MONDAY, March 8.—Annual Meeting of the United Horticultural Benefit and Provident Society, at the Royal Horticultural Hall, Westminster.

TUESDAY, March 9.—Royal Horticultural Society: Fruit, Floral, Orchid, and Narcissus Committees meet at 12 o'clock; Lecture at 3 o'clock on "Bulb Growing in Holland," by Mr. W. S. Murray; Scientific Committee at 4 o'clock.

CATALOGUES RECEIVED.

BARR AND SONS, KING STREET, COVENT GARDEN.—As everything is arranged in alphabetical order in this very useful catalogue, it is an easy matter to find what one wants. The list is a comprehensive one, as may be gathered from its sub-title of "Seeds for all Seasons and Climates."

PAUL AND SON, WORMWOOD STREET, E.C. The Roses and Shrubs produced by the Cheshunt firm have rather over-shadowed the seed business carried on in the City. The catalogue also contains lists of hardy flowers, dahlias, and chrysanthemums.

ROBERT VEITCH AND SON, EXETER.—Vegetable novelties figure largely in this seed list, but the most prominent feature is the new Golden Glory calceolaria.

R. H. BATH, LIM., WISBECH.—Flower and vegetable seeds.

HOGG AND ROBERTSON, MARY STREET, DUBLIN.—This firm's seed catalogue is as useful, interesting and complete as its bulb catalogue, and we need say no more.

DANIELS BROTHERS, LIM., NORWICH.—Flower and vegetable seeds.

W. ATLEE BURPEE, AND CO., PHILADELPHIA, U.S.A.—A most interesting catalogue [illegible] it is so different in style and arrangement [illegible] tish lists. It is crowded with illustrations [illegible] colours, and deals with a very wide range [illegible] fruits, and vegetables.

GEO. COOLING, AND SONS, BATH.—An excellent seed catalogue.

VILMORIN-ANDRIEUX AND CO., QUAI DE LA MEGISSERIE, PARIS.—A very comprehensive and business-like seed list.

HERD BROTHERS, PENRITH.—Flower and vegetable seeds.

A FINE TABLE AND EXHIBITION PEA.

WEBBS' STOURBRIDGE MARROW PEA
(Second Early). 2s. 6d. per quart.

"Upwards of 60 varieties of Culinary Peas have been grown here during the last 7 years, including most of those for which quite fancy prices were asked, but for cropping, flavour, and size, I feel bound to say I have not yet found one to excel Stourbridge Marrow, which possesses these attributes in a marked degree. The pods, which are often upwards of 5 inches in length, and usually borne in pairs, are unlike some of the more recent introductions in that they are always well filled with peas, many of which equal Horse Beans in size. Even when getting rather older than we like to see them for table, they are usually of sweet flavour."—F. R. Castle in "The Gardener," Jany. 9/09.

WEBB and SONS, The King's Seedsmen, WORDSLEY, STOURBRIDGE.

LAXTON'S FRUIT TREES and STRAWBERRIES.—Thousands of beautifully-trained trees to select from in all shapes. Fully illustrated Catalogue post free. LAXTON BROTHERS, Fruit Specialists, Bedford.

SUTTON'S PIONEER PEA.
One of the best varieties in the dwarf section of the early class.
Per pint, 2s.; per quart, 3s. 6d., post free.
Mr. W. H. Yates, Gardener to A. E. Scott, Esq., writes: "I should also like to say a word in favour of your Pioneer. Grown here for the first time this year, it presented a grand sight; the haulm, less than 2 feet in height, being covered with fine pods, all well filled with excellent peas. In my opinion this is one of the very best Peas of recent introduction for early work."

SUTTON AND SONS, THE KING'S SEEDSMEN, READING.

NOW IS THE TIME TO PLANT
(the best time of the whole year)
KELWAY'S BEAUTIFUL BLUE DELPHINIUMS.
Hardy, and flourishing in every garden, they are the STATELIEST of PERENNIAL PLANTS for borders or beds; these celebrated improvements are invaluable for their introduction of that precious colour—blue—in masses to the garden. KELWAY and SON developed this race, and they should be procured direct from the Royal Horticulturists, Langport.

KELWAY'S IMPROVED DELPHINIUMS are now ready, strong plants, in choice named selections. Collection "B," 15s. per doz. Collection "D," 42s. per doz. Delivery free for remittance with order. KELWAY and SON, The Royal Horticulturists, Langport, Somerset.

FRANCO-BRITISH EXHIBITION, 1908. ONE of the ONLY THREE Gold Medals (or Higher Awards) (open to the whole world for permanent exhibits) awarded by the International Jury, and confirmed by the Governing Council was awarded to Kelway and Son; vide the AUTHORISED LIST published in the Press.—KELWAY and SON, Langport, Somerset.

FOR PRESENT PLANTING.

PLANTERS of FRUIT TREES should write for our fully descriptive catalogue and supplement, 6d., post free; and gratis to customers.

Well-ripened trees of all kinds, and our large, developed specimens of Vines, Figs, Peaches, and Nectarines, are especially good.

An inspection solicited.

TO-DAY! AND FOR YEARS AND YEARS PAST the XL ALL Specialities are and have been the best on the market. Where is the Gardener who does not pin his faith to one or the other of these celebrated Insecticides or Fertilisers? XL ALL FERTILISER has pleased all who have used it this season. The Sales of XL ALL FUMIGATOR prove that it is more popular than ever. XL ALL LIQUID NICOTINE INSECTICIDE is always spoken of by gardeners and growers as the most deadly to Mealy Bug, Thrip, etc. XL ALL WINTER WASH for dormant Trees acts like magic, clearing the Trees and Bushes of all Insects' Eggs, Moss, and Fungoid Growths. XL ALL LAWN SAND, a weed eradicator and fertiliser for weedy and poor lawns. XL ALL WEED KILLER used once a year "No weeds can live." Please ask your Nurseryman, Seedsman, or Florist for a copy of my small pink list, giving particulars of these and many other XL ALL Preparations, which can be obtained from the Horticultural Trade throughout the World. G. H. RICHARDS, Manufacturer and Patentee, 234 Borough High Street, London, S.E.

THE GARDENERS' MAGAZINE.

NOTES OF THE WEEK.

Combating the Woolly Aphis.

By the issue on the earliest possible date of the tenth report of the Woburn Experimental Fruit Farm, the editors, the Duke of Bedford and Mr. Spencer U. Pickering, have rendered a service of great practical value to the general body of fruit growers, and one that will not fail to be fully appreciated. This report is devoted to the observations made during 1908 on the treatment of fruit trees for insect pests, and as a consequence of the increasing importance which is now being attached to the spraying of fruit trees, it was considered advisable to publish the results at once instead of waiting till the subject matter for a more extensive report on the combating of insect pests had been accumulated. Of special interest are the results of the experiments in the eradication of the woolly aphis, one of the most troublesome of the pests that infest fruit trees: the treatment for psylla, which also does much damage when allowed to sap the vitality of the trees unchecked; and the treatment for caterpillars of various kinds that prey upon the leafage of the different species of fruit-bearing trees; but there is not a line undeserving of the most careful perusal by those engaged in fruit production. As so well known to the general body of fruit growers the infestation of apple stocks with the woolly aphis or American blight is a common occurrence, involving much trouble and some loss to both trade and private growers, owing to the difficulty in eradicating the pest by means of the methods hitherto adopted. This difficulty has been greatly accentuated by the fact that the insect exists in the active adult form on the roots both in winter and summer, and that the root form migrates to the branches during the summer months. Hence the cause of the failure to rid the trees of the pest when treatment is confined to those parts only above ground. It is suggested in the report that nursery stock, especially that obtained from abroad, should always be treated for woolly aphis before being planted, and that it is advisable to treat worked trees in the same way. Usually the treatment adopted is fumigation with hydrocyanic acid; but as this is dangerous to the operator, and not always satisfactory, experiments were made at Woburn with the object of obtaining some simpler and more efficacious method of treatment. Directions are given for fumigating the trees with hydrocyanic acid, and those growers who have a preference for the method, or may be desirous of trying it, are thereby placed in possession of the details of the best course of procedure. In the eradication of these and some other of the enemies of fruit trees, it is essential that the eggs as well as the insects should be destroyed, and at Woburn hydrocyanic acid has failed to accomplish their destruction. Not only has this been the case in the experiments with the woolly aphis, but it has been equally ineffective in the case of the black currant mite and mussel scale. With the last-named insect a double dose of the gas was ineffectual, but Professor Theobald, who originally reported similar failures in the case of the woolly aphis, has recently obtained satisfactory results by doubling the proportions of cyanide hitherto recommended. Whether similar success would in all cases be obtained in the case of the pest under consideration by double strength is doubtful, and the discovery of a more simple and less dangerous method of procedure is a matter of much importance. With reference to the manner in which the experiments were conducted, the report states that about three thousand crab and paradise stocks which had been worked in 1906 had proved to be badly infested with woolly aphis; these had been treated throughout 1907, so far as the parts above ground were concerned, by repeated painting with methylated spirits without any permanent effect. They were in consequence taken up in January of last year, and the greater proportion of them fumigated in a greenhouse. Only a portion of the stocks that had been worked with Cox's Orange Pippin were fumigated, the rest being treated in various other ways. All the treated trees were planted side by side and kept under close observation. Each batch of Cox's Orange Pippin consisted of forty trees. One batch was fumigated, and of these 20 per cent. were infested with the woolly aphis on June 14 and July 2, and 63 per cent. on September 22. Three batches were treated with different forms of paraffin, by immersion for five minutes, and left on the ground thirty minutes before planting. The trees immersed in the comparatively non-volatile oil, Woburn Solar Distallate, were all killed; and of those treated 67 per cent. of the scions and 12.5 per cent. of the trees were killed. White Rose oil gave similar results. In the treatment with No. 4, Pratt's Motor Spirit, the woolly aphis was completely eradicated, and 10 per cent. of the scions and 5 per cent. of the trees died. Therefore, "a very light oil, such as petrol is the only form of paraffin that can be used in this way." Two batches were treated

MR. T. B. FIELD.

with the Woburn wash, the trees of one being wholly immersed, while those forming the other had the branches only treated. Of the first batch 5 per cent. showed infestation on June 14, but were quite free July 2 and September 22, and 10 per cent. of the scions and 2.5 per cent. of the trees died. In the second batch the pest was present on 17.5 per cent. of the trees on June 14, but on July 2 and September 22 the trees were quite free from it. and the deaths were 5 per cent. of the scions and 7.5 per cent. of the trees. The experiments in the use of hot water in the eradication of the woolly aphis are to us of special interest, for more than thirty years ago we strongly recommended in these pages the use of hot water as an insecticide. Two batches were treated with hot water, one being immersed five minutes in water at a temperature of 125 degrees and the other ten minutes in water at 115 degrees, the temperature being maintained throughout the immersion by the addition of hot water as required. The first set of trees were wholly free from the woolly aphis on June 14 and July 2, but 15 per cent. were infested on September 22; 7.5 per cent. of the scions, and 7.5 of the trees died. The trees in the second of the two batches were quite free from insects throughout the season, and 5 per cent. of the scions and 25 per cent. of the trees died. From this brief summary it will be seen that the most effectual of the remedies were petrol, and hot water at 115 degrees, and it is stated that their superiority was even more manifest in November. Woolly aphis is described as having multiplied to a remarkable extent late in the season, and by the end of the month mentioned 98 per cent. of the cyanided trees were infested by insects. Of those treated with petrol only four had slight traces of them, and of those immersed in hot water at 115 degrees only one was affected. They also made the most healthy growth; but the trees immersed in water at a temperature of 125 degrees made but poor progress. The bath of ten minutes at a temperature of 115 degrees is recommended as the best treatment of nursery stock before planting. No doubt hot water treatment would be an effectual way of clearing established trees of the insects and their eggs, but it is extremely doubtful whether the practical difficulties attending the process can be overcome.

Mr. T. B. Field, whose portrait we give in this issue, is one of the best known of English gardeners, and at the present time occupies a prominent position among the practical horticulturists in the great gardening district of which Norwich is the centre. After serving an apprenticeship, and occupying positions in several of the leading gardening establishments, Mr. Field went to Spy Park, Wilts, as foreman. Here he remained until three and a-half years later he was appointed head gardener to Sir Henry Tyrwhitt, Bart., at Ashwellthorpe, where, as well known to our readers, he now is. Within a short time subsequent to the engagement Sir Henry removed to his Shropshire seat, Stanley Hall, Bridgenorth, and Mr. Field accompanied him. While in charge of the gardens of this interesting and grand old seat he engaged largely in the cultivation of orchids, roses, and herbaceous plants, and did some amount of exhibiting, and achieved a full measure of success. When at Stanley Hall Mr. Field was elected a member of the first committee of the Shrewsbury Flower Show. Taking an active part in horticultural work in the Bridgenorth district, Mr. Field was in acknowledgment thereof presented with a gold watch and other tokens of respect on his leaving Stanley Hall. On the death of Sir Henry Tyrwhitt in the year 1894, his widow, the Baroness Berners, returned to her own seat, Ashwellthorpe, and Mr. Field resumed the charge of the gardens there. Joining the East Anglian Horticultural Club, one of the most influential of the societies of its class in England, he soon attained to the position of acting vice-president, and this position he still occupies. In connection with this society there was a strong botanical section, of which Mr. Field was president, but this has since been merged into the work of the Norwich Castle Museum Society, on the committee of which Mr. Field has a place. School gardening occupies a prominent position in the educational work of the City of Norwich, and in this Mr. Field takes a keen interest, and at the annual exhibitions he may be seen addressing the scholars and their parents on garden management. Mr. Field has accomplished much splendid work, both in the gardens under his charge and in the performance of his duties, and he regards his success as being largely due to the kindness and consideration of his employers during the thirty-eight years he has been at Stanley Hall and Ashwellthorpe.

Fruit Imports in January last were remarkable for the number of decreases in the quantities, but the values were so well maintained that the total increase in value closely approached £200,000. The imports of apples amounted to 325,663 cwt., of the value of £215,681, these figures representing a decrease in quantity of 10,549 cwt., and an increase in value of £25,219, as compared with the corresponding month of last year. Apricots and peaches aggregated 273 cwt., of the value of £1,813, against 3,608 cwt. of the value of £9,776 in January, 1908. Bananas show an increase in number of 23,028 bunches, and a decrease in value of £5,728, the totals having been 341,804 bunches and £83,025 respectively. Grape imports dropped from 1,622 cwt., of the value of £4,475, in January, 1908, to 948 cwt., of the value of £4,414 last month; these figures being of interest, for with a drop of 674 cwt., the decrease in value was only £61. In the imports of pears, there was a decrease in quantity of 2,438 cwt., and in value of £3,497, the totals having been 433 cwt., of the value of £614. Plums also show a considerable decrease, the quantities having been 87 cwt., and the values £329, against 362 cwt., of the value of £847 last year. In the imports of unenumerated fruits there was an increase in quantity of 3,803 cwt., and in value of £6,374, the totals having been 5,339 cwt., and £9,012 respectively. The aggregate value of the January fruit imports was £836,028, or an increase of £197,545.

National Chrysanthemum Society.—At a committee meeting held at Carr's Restaurant on the evening of Monday last, the president, Sir Albert Rollit, being present, it was decided that the prizes awarded at the society's shows last year should at once be paid at the rate of ten shillings in the pound. This will absorb the reserve fund and all other money in hand, with the exception of about £20. The society has a rule providing for the pro rata payment of prizes according to the funds in hand: but this is the first time the rule has been put into operation. Had the Crystal Palace Company paid the amount due according to the agreement under which the shows were held, the society would have been able to pay its prizes in full, and have had an excellent balance on the right side. There is abundant and excellent work for the N.C.S. to perform, and we trust that those intimately associated with its management will not be unduly depressed, but will proceed forthwith to effect such changes as are necessary to again place the society in a satisfactory position. Should the executive be successful in formulating a policy adapted to the changed circumstances, we hope all who are interested in chrysanthemums and chrysanthemum culture will rally round the society, and give it the most substantial financial and moral support.

Myosotidium nobile.—Mr. S. W. Fitzherbert writes: With reference to the illustration of a fine specimen of the New Zealand forget-me-not that appeared on page 87, I may mention that I have lately discovered that numbers of self-sown seedlings are springing up around the old plant.

A Camping Tour through Syria.—At the next meeting of the Royal Horticultural Society, to be held on February 23, Mr. Arthur W. Sutton, V.M.H., F.L.S., will give a lecture at 3 p.m., entitled "A Camping Tour through Syria to Petra in Arabia." The lecture will be freely illustrated with beautiful lantern slides. Having already heard the lecture and seen the slides, we confidently assure our readers of the great pleasure, interest, and instruction they will derive from attendance on Tuesday next. Unless we are very much mistaken, it will be necessary to arrive early at the lecture room to ensure a seat.

Garden Roses.—A lecture on "Garden Roses," fully illustrated with lantern slides, will be given by Mr. George Gordon on Saturday evening (February 20) before the Haslemere branch of the British Gardeners' Association. The meeting will be held at the Co-operative Hall, Haslemere, and the chair will be taken at 7.30 p.m.

Sawbridgeworth Oranges and Lemons.—As so well-known to our readers, Messrs. T. Rivers and Son have for many years devoted special attention to the cultivation of oranges, lemons, and closely allied fruits, and have achieved so much success as to prove to demonstration the practicability of successfully growing these fruits for dessert in this country. At the meeting of the Royal Horticultural Society at Vincent Square on Tuesday next, the 23rd inst., the firm will exhibit a group of oranges, lemons, and lime trees in pots and also fruit-laden branches cut from other trees. These branches will be cut from eighteen trees planted out in a span-roofed house 60 feet long, and now bearing upwards of 800 fine fruits.

The "Botanical Magazine" for February contains a double-page illustration of Alpinia bracteata, a showy relative of the Ginger; and page illustrations of Oligobotrya Henryi; the beautiful violet-blue Eranthemum Watti, figured in these pages in 1901; Pinus Bungeana, a conifer that appears to be a success near towns; and Sorbus Vilmorini, a new Chinese shrub.

CANDYTUFTS FOR THE ROCK GARDEN.

The perennial candytufts form an extremely useful group of plants for the rock garden, as with abundant flower production they combine evergreen foliage and a free yet compact habit of growth. Some of the stronger growing species, such as Iberis semperflorens, are of much value for massing in the garden with other spring flowers, and the formation of bold groups along the front of the mixed border, and in many gardens they are largely grown for one or both of these purposes. It is, however, for their use in the rock garden that reference is now being made to them; and, at the outset, it may be stated that with but few exceptions they have such constitutional vigour as to be especially adapted to the requirements of those who are not experienced in the cultivation of the more delicate alpines. While growing freely under conditions not particularly favourable to plants from Alpine regions, they are wholly free from coarseness, and they are sufficiently attractive at all times to justify their association with the choicest of the denizens of the Alps.

CANDYTUFTS IN THE ROCK GARDEN AT MYDDLETON HALL.

Of the several species belonging to the group, the best known is I. sempervirens, which has a comparatively vigorous habit, and is especially adapted for bold ledges and clothing the face of the rocks with verdure. It can be readily raised from cuttings of the new growth when the stems have become moderately firm, which is usually the case in July, or from seeds. The second is the simplest of the two methods of propagation, but it is not the one that can be the most strongly recommended when a few plants are required for the rock garden. Seedlings differ considerably, both in habit and in the size of their flowers, and therefore a good type should be selected, and the plants be raised from cuttings. When the growth can be allowed to extend freely without the risk of an invasion of the quarters of small growing kinds, it should be allowed to do so, especially when the position is such that the shoots drape the face of the rocks with greenery. Otherwise, it should be kept well within bounds, and this is best done when the plants are going out of bloom. If a little shortening of the more vigorous shoots is done each year at the period suggested, the plants can be kept well within bounds without their showing signs of having been cut back, and they will annually produce a profusion of their snow-white flowers, as will indeed those which are allowed to extend freely.

Highly meritorious also are I. correæfolia, I. gibraltarica, I. saxatilis, I. semperflorens, and I. tenoreana, all of which thrive under much the same conditions as I. sempervirens. I. correæfolia is a garden hybrid, growing to a height of about twelve inches, and producing a profusion of large white flowers in flat heads. As it does not reproduce itself true from seeds the stock should be increased by means of cuttings. I. gibraltarica is stronger in growth than the last-named, and it is rather straggling in habit. The flowers are white, frequently suffused with pink, and produced in large corymbose heads. Being rather tender the plants should have a warm, somewhat sheltered position. I. saxatilis has a height of five or six inches, is compact in habit, and bears a profusion of its neat heads of white flowers. I. tenoreana is of value for the distinct shade of colour it affords, the flowers being white, changing with age to rose-purple. It should have a warm, dry position.

The illustration accompanying these notes represents a warm slope in the beautiful rock garden of E. A. Bowles, Esq., F.L.S., Myddleton Hall, Waltham Cross, on which are several fine masses of the most noteworthy of the perennial candytufts.

SEASONABLE WORK IN THE GARDEN.

Although there is at all times plenty of work requiring attention in gardens of any pretensions, there is usually a greater strain on the staff during the spring months than at any other season, and should there be any extra unforeseen work crop up, causing delay just at a time when all hands are needed to prepare the ground for sowing and planting, the crops suffer accordingly. When the soil cannot be worked to advantage it is well to leave sowing and planting alone for a few days; the ground, however, should always be prepared in readiness to receive the crop, so that when a favourable opportunity does present itself, the work may be accomplished with as little delay as possible. When the weather is unfavourable for working on the land, other things should be pushed forward. Fruit trees, both on walls and in the open, will at this time of the year need attention, and where pruning and nailing have not been completed this work should be pushed forward without further delay, for when left until the spring it is often hurried over and not done in a satisfactory manner. Those who are anxious to produce fine samples would do well to take this into consideration. Spraying is one of those operations that may be done with advantage now, and there is such a variety of spraying machines on the market that there should be no difficulty in selecting one to suit all purposes, and there is no lack of insecticides and alkali preparations for washing the trees with during the winter. The only care necessary with any of these alkali preparations is to see that none of it gets on the hands or clothes, as they are of a very burning nature. To prevent this a pair of gloves and an old mackintosh are all that is necessary for the operators to use to prevent any unpleasantness afterwards.

Those who do not possess a spraying machine may have the garden engine fitted up for that purpose. If the nozzle of the engine be taken off and a piece of stout hose pipe attached, so as to reach up the wall or round the trees, and this has attached to it a spraying nozzle with a length of brass or iron tubing, there is no difficulty in spraying trees of fair dimensions. Of course it would take two men to use a sprayer of this description, whereas with a knapsack sprayer one man can do the work with ease. There can be no two opinions about trees that are well looked after producing the finest fruit, and as a stronger insecticide can be applied in winter when the trees are dormant much labour may be saved by doing the work then than by waiting until the foliage and fruit are infested. It is not the greatest quantity of the preparation used that does the most good, as a lot of it may be wasted by a careless operator. So long as every portion of the tree and wall is moistened that is sufficient. If it is found that one dressing is not effective, give another, but spraying with these strong alkali solutions should not be deferred until the sap is rising in spring.

In the South, and on dry gravelly soils, trees against walls are apt to suffer from the effects of red spider in hot seasons, a spraying at this time of the year will cleanse not only the wood but the brickwork likewise, and thus save endless trouble when the trees are in fruit. All such work can be done more thoroughly at this time of the year than later on, when the pressure of work is so much greater. Some have an idea that peach growing in this country is a lost art unless the trees are protected with glass, but such is not the case, for where there is due attention paid at all seasons of the year, more especially in the winter and spring, as fine fruit as of old may still be produced, but pressure of work in other departments prevents many gardeners devoting so much attention to them as they would like to do, hence the reason of so many failures. In many places periodical lifting is absolutely necessary to prevent the roots from going down into the cold uncongenial soil beneath, and this entails considerable labour if such work is to be done thoroughly. The blossom must also be protected from frost in spring. It is useless to half do the work, and whatever is worth doing at all is certainly worth doing thoroughly. It is not altogether the climate that is to blame, for in many instances it is failure to pay due attention to the trees' requirements at the proper time. We hear much about black currant mite, but if the trees are kept healthy this need not trouble the grower very much. It is when worn out and neglected that we find the bushes most affected, and it is on such that this pest obtains the upper hand. The present is a good time to examine the trees and remove all large, swollen buds, which should be destroyed at once, for later on in the majority of places time will not permit of such work being done. When all the swollen buds have been removed give the bushes a spraying.

Trees growing against walls are more subject to pests of all kinds than those growing in the open, as there is a much greater harbour for them, more especially where the mortar is loose. All old walls should be pointed whenever the trees can be liberated from them.

At this time of the year replanting of box edging should be taken in hand, for nothing adds more to the appearance of a kitchen garden than neat, well-kept box edging. Choose mild weather for the work as a man can do more under favourable conditions than when cold east winds are blowing, or biting frosts are benumbing his fingers. If all such work is well in hand at the present time, the workmen will be at liberty later on to pay more attention to the general routine of gardening operations. Spring time in the garden, though it brings much extra work, is accompanied by many pleasures, for then everything seems to put forth new life, and when one is able to look round complaisantly and watch things growing without feeling that there has been something neglected that ought to have been done weeks back, there is a satisfaction in knowing one is abreast of the times. But when one is confronted at every turn with something that needs immediate attention all the pleasure departs. There is far more satisfaction in a garden that is well kept though it be of small dimensions, than in one of considerable extent that is ill-cared for.

Gardening when conducted for pleasure, not profit, is, or should be, done in the most approved manner. When carried out on these lines, whether large or small, everything should be of the finest quality possible, whether it be flowers, fruit, or vegetables, and the aim should be to do all things in the right season, and have everything in its proper place, and unless this is strictly carried out, it is next to impossible to give satisfaction. There can be no pleasure to the employer in seeing plants half starved, trees badly trained, walks covered with weeds, and lawns untidy, which is too often the case where there is not sufficient interest taken to attain these ends.

H. C. Prinsep.

Buxted Park Gardens.

FINE EXAMPLES OF TAP-ROOTED VEGETABLES.
Shown by Mr. A. Gentle at a recent R.H.S. Meeting.

FINE TAP-ROOTED VEGETABLES.

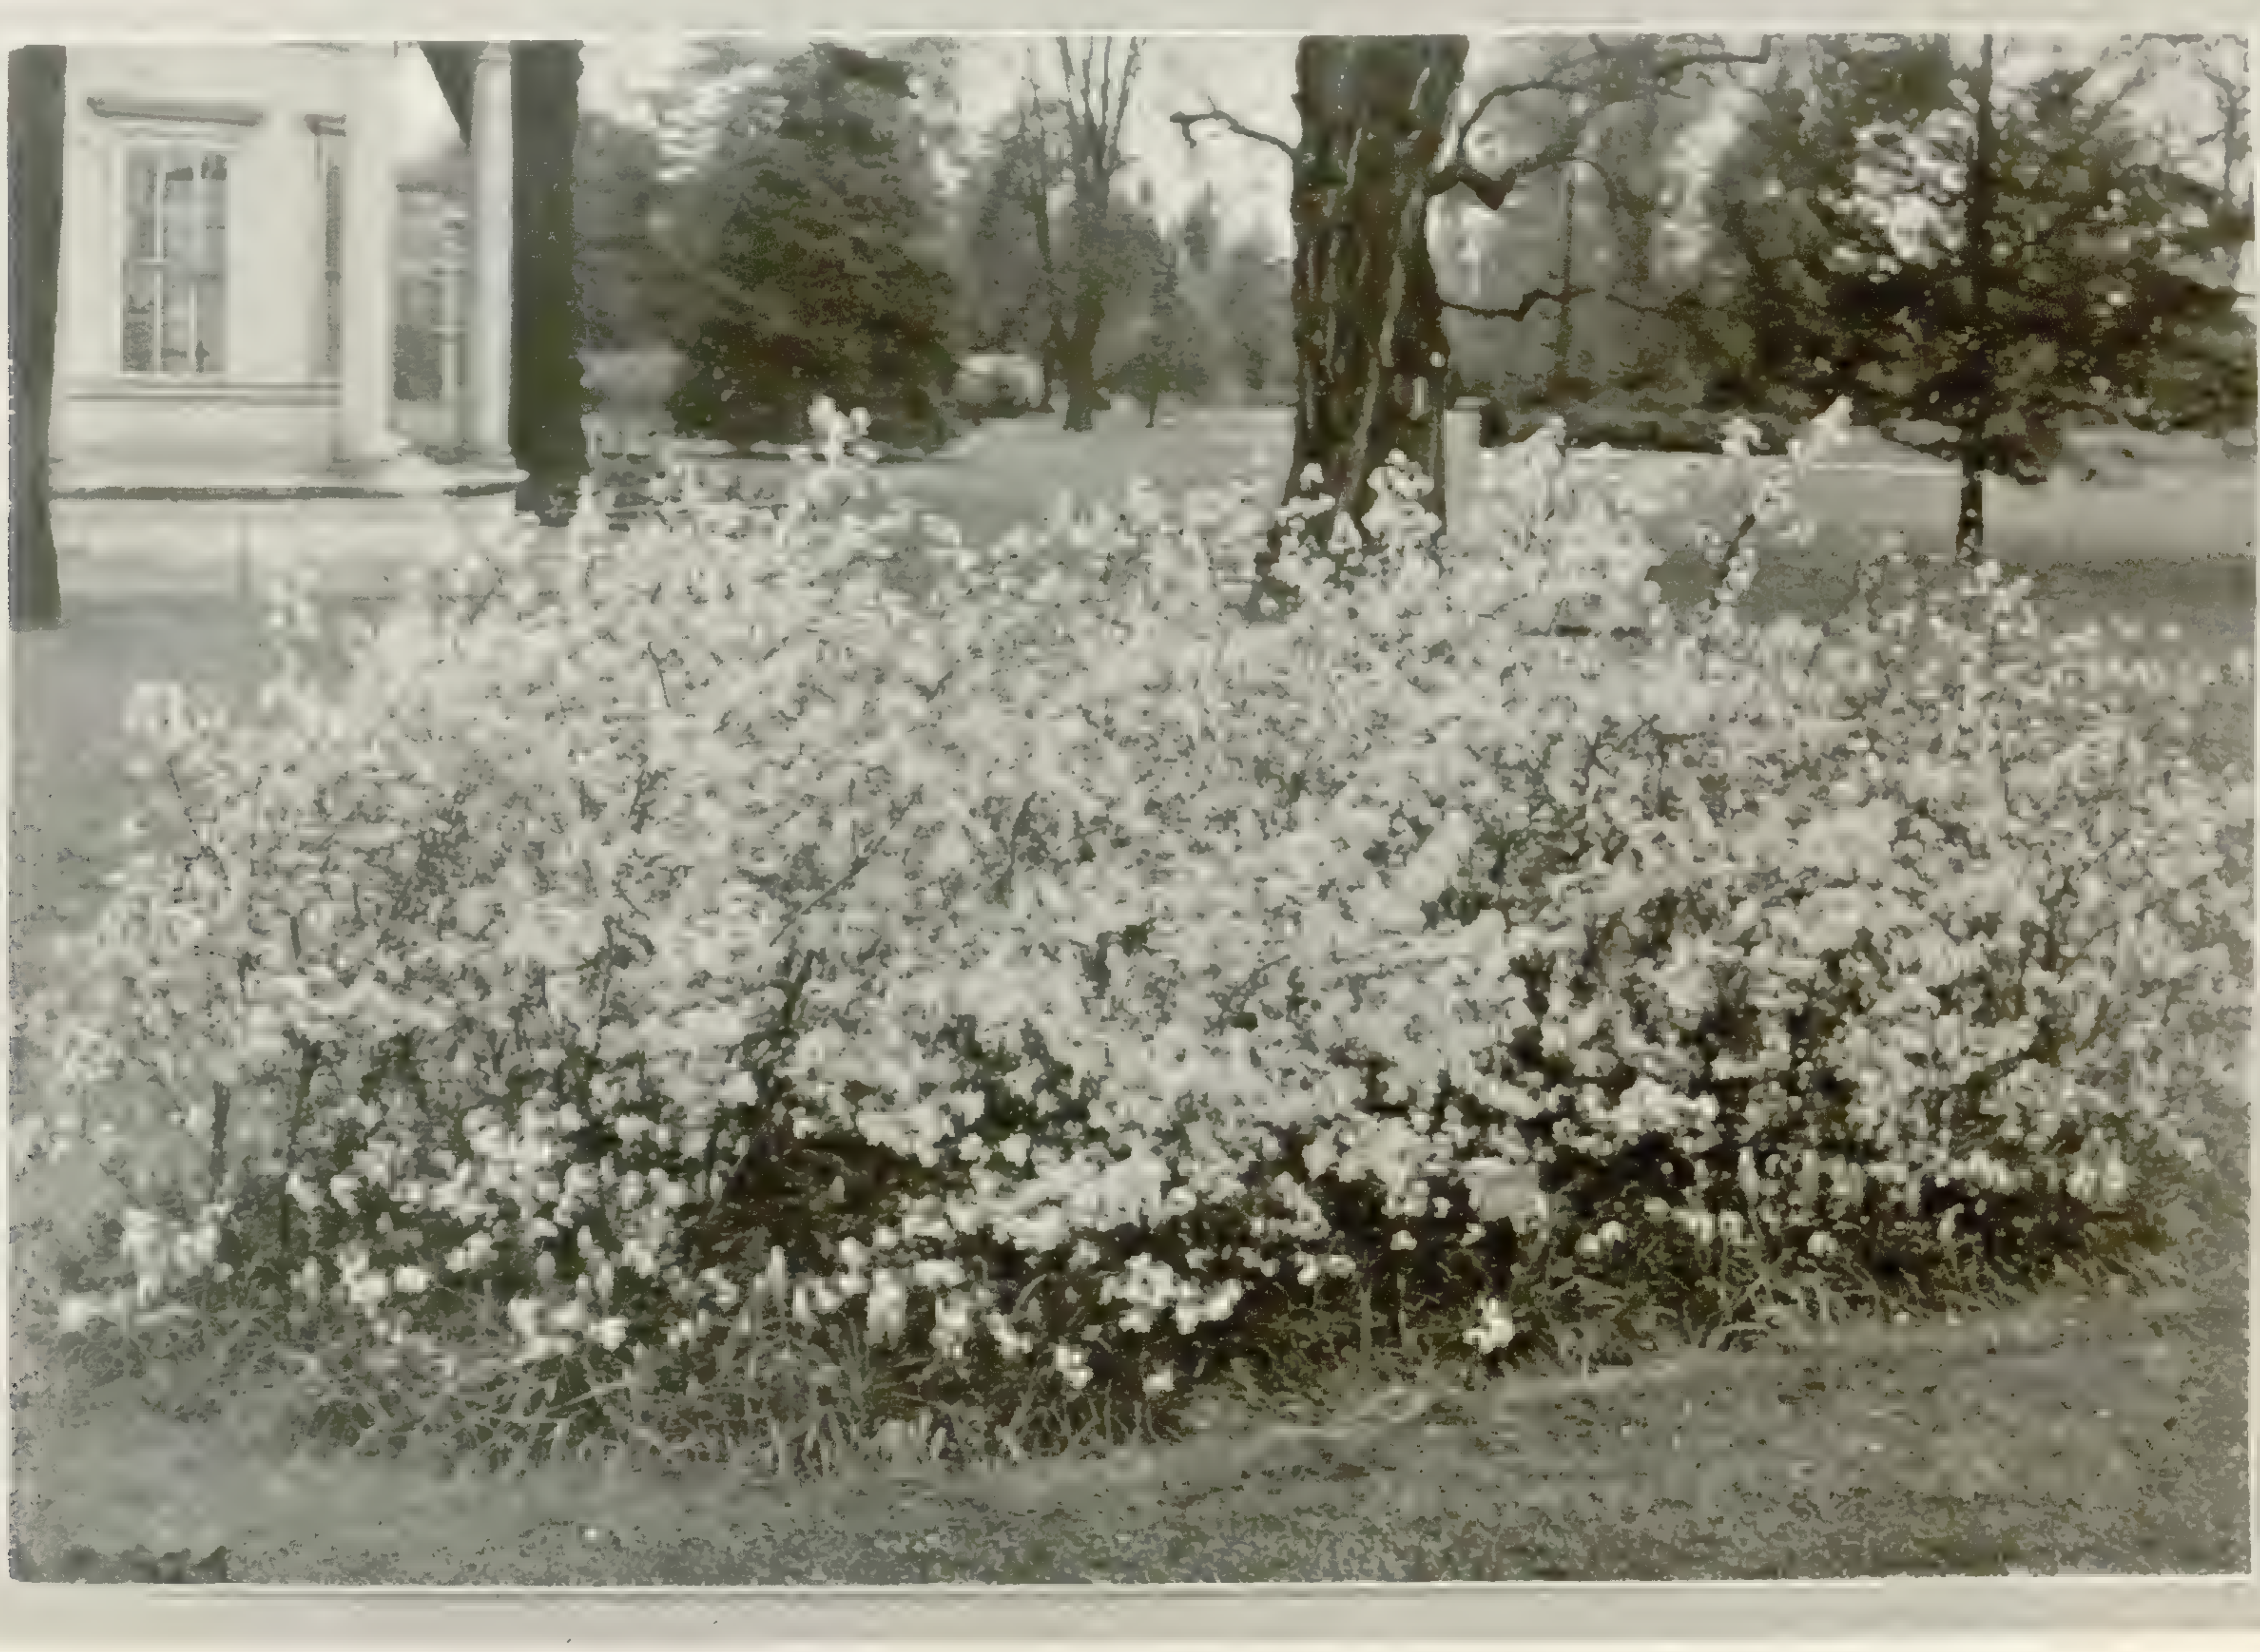
The great secret of success in the production of garden root crops of the highest class lies in deep cultivation and a thorough pulverisation of the soil. There is no royal road to success, although in some gardens and on some kinds of soil success is easier to attain than on others. In very heavy, wet soils and in very shallow, dry ones, the difficulties in the way are considerable, more particularly in the latter case. But enthusiastic growers will find a way of producing good crops, no matter how unpromising the conditions. Trenching and heavy manuring, followed by the cultivation of some strong feeding crop, such as celery, cauliflowers, beans, and the like, will do much to bring soil into a fine tilth for the production of clean, shapely roots. Old potting soil, road sweepings, leaf-mould, burnt refuse, and other materials will ameliorate a heavy soil, and also deepen a shallow one, but, after all, deep cultivation is the great thing, and it is surprising how a shallow soil may be improved by frequent working and breaking up the subsoil, together with the usual manurial dressings. That famous grower, Mr. E. Beckett, is a great advocate of trenching, and he has many imitators and followers in these days. One who has been specially successful with tap-rooted vegetables is Mr. Gentle, gardener to Mrs. Denison, Little Gaddesden, Berkhamsted, and the beet, carrots, and parsnips he exhibited in London recently were regarded by competent authorities as being as near perfection as possible. Of course, one must not minimise the importance of fine strains of roots or other crops, for, unless the strain is a good one, a great deal of time and labour are wasted. The vegetables shown by Mr. Gentle were all fine types and from Messrs. J. Carter and Co.'s selections.

Index to the "Gardeners' Magazine," 1908.—Those readers who have preserved the 52 numbers of the Gardeners' Magazine for 1908 with a view to having them bound for future reference, can obtain Handsome Cloth Binding Cases from the publishers, 148 and 149, Aldersgate Street, London, price 2s., post free. The index, with title page, is now ready—price 2d., or by post 2½d. The volume bound complete may also be had, price 12s. 6d., by post 13s. 4d.

THE DWARF JUNE BERRY.

The swelling buds of the almonds remind us of the charms of trees and shrubs remarkable for the beauty of their flowers, and of the many delightful colour effects that may be enjoyed during the next few months in gardens in which they are adequately represented. Already may be seen in conservatory and greenhouse displays of lilacs, magnolias, forsythias, viburnums, and similar subjects; and before the flowers of the last of the forced plants have lost their beauty, and other subjects utilised in beautifying these structures, several kinds will be yielding of their wealth of floral beauty in the garden. The June Berry (Amelanchier canadensis) and its varieties, do not occupy a place among the earliest of the flowering trees and shrubs; but they are quite early in blossoming, and so free in the yield of their floral beauty, and, moreover so elegant in aspect, as to possess much value in the adornment of the garden. Not only are they specially attractive during the spring months, but in the autumn the leaves are a bright orange hue, and, whether in groups or occupying isolated positions, the trees present an attractive appearance, more particularly when seen under the soft rays of the sun in the rapidly declining days of the year.

The June Berry is the best known of the several species in cultivation, and without doubt it is the finest of them. There are several well-marked varieties of this elegant tree, and one of the best is the Dwarf June Berry (A. canadensis alnifolia), which, in some of the books, has specific rank. This was introduced from the North West of America about twenty years ago, is dwarf in growth, and produces in great profusion its racemes of pure white flowers. The comparatively dwarf habit renders it of much value for cultivation in beds, as so well demonstrated in the Royal Gardens, Kew, by the fine example herewith illustrated. In private gardens, where the beds occupying a prominent position should yield a continuous display of flowers over the longest possible period, it will be well to select a site for a lawn group in a somewhat remote position. Beds of this and other shrubs may have their attractions greatly enhanced, by carpeting their surface with muscari or some other bulbous plant of dwarf growth that blooms early in the spring. The muscari used in carpeting the bed at Kew is the variety of M. conicum known as Heavenly Blue.



THE DWARF JUNE BERRY, AMELANCHIER CANADENSIS ALNIFOLIA, AS GROWN AT KEW.

ESPALIER PEAR TREES.

The espalier mode of training the pear is specially suitable for gardens in which space is inconveniently limited, and where it is particularly valued, for trees of this description occupy but little space as compared even with pyramids, and they may be advantageously planted at the back of flower borders that margin walks, to screen from view crops of vegetables, or other less elegant objects. Other advantages to be gained by growing this form of tree are that the blossoms can be protected from frosts, and the fruit from birds, by simple means and little trouble. Sheets of tiffany will answer in one case, and closely meshed wire netting in the other, and by careful treatment each of these appliances will last for years. Five feet is a convenient height for this kind of tree, and the branches may be trained horizontally, vertically, or obliquely, as desired. The best kind of support is a strong iron fence, with bars placed at distances apart suitable for the branches being fastened to them. For preference, the fence should run north and south, so that each side of the trees, together with the whole of their fruit, can derive an equal share of benefit from the sun. In securing trees for planting, it is advisable to have those of the usual planting size worked on the quince stock, for although no great amount of skill is required in raising them from maidens, more is lost than gained in doing so in private gardens.

Probably no kind of fruit tree in private gardens is so generally neglected as is the espalier; in some cases the only cultural attention that it receives is pruning and training. The surface roots are either mutilated by the spade, from the ground being more or less deeply dug up to near its stem, or they are robbed of nourishment by flowering plants, vegetable crops, or other similar subjects. Further, the roots are rarely lifted out of injurious subsoils, carefully pruned, or specially supplied with manure.

Though some varieties, owing to their habit of growth, form neater trees than do others, most pears do well as espaliers in localities suitable to the fruit. The exceptions are kinds that require warm positions upon walls to bring them to perfection, such as Winter Nelis, Bergamotte d'Esperen, Glou Morceau, Beurre de Jonghe, General Todleben, Nouvelle Fulvie, Marie Benoist, Beurre Rance, Thompson's and similar varieties. T. Coomber.

The Hendre Gardens.

Nymphæa pygmæa Helvola.

One of the most delightful of all the smaller water lilies is Nymphæa pygmæa Helvola, a dainty little flower, which appeals to all lovers of the beautiful as they see it floating on a little pool or tank, its prettily shaped leaves and bright little soft yellow flowers fascinating all who see it for the first time, except, it may be, those who are devotees of size in flowers. Only an inch or two across, those of Helvola are almost fairylike among flowers of its class. This bright little water lily is absolutely hardy, and can be grown in water of a depth of from a foot to eighteen inches. A little good loam at the bottom will suit it, and planting may be effected from March until May.—S. Arnott.

BUDS.

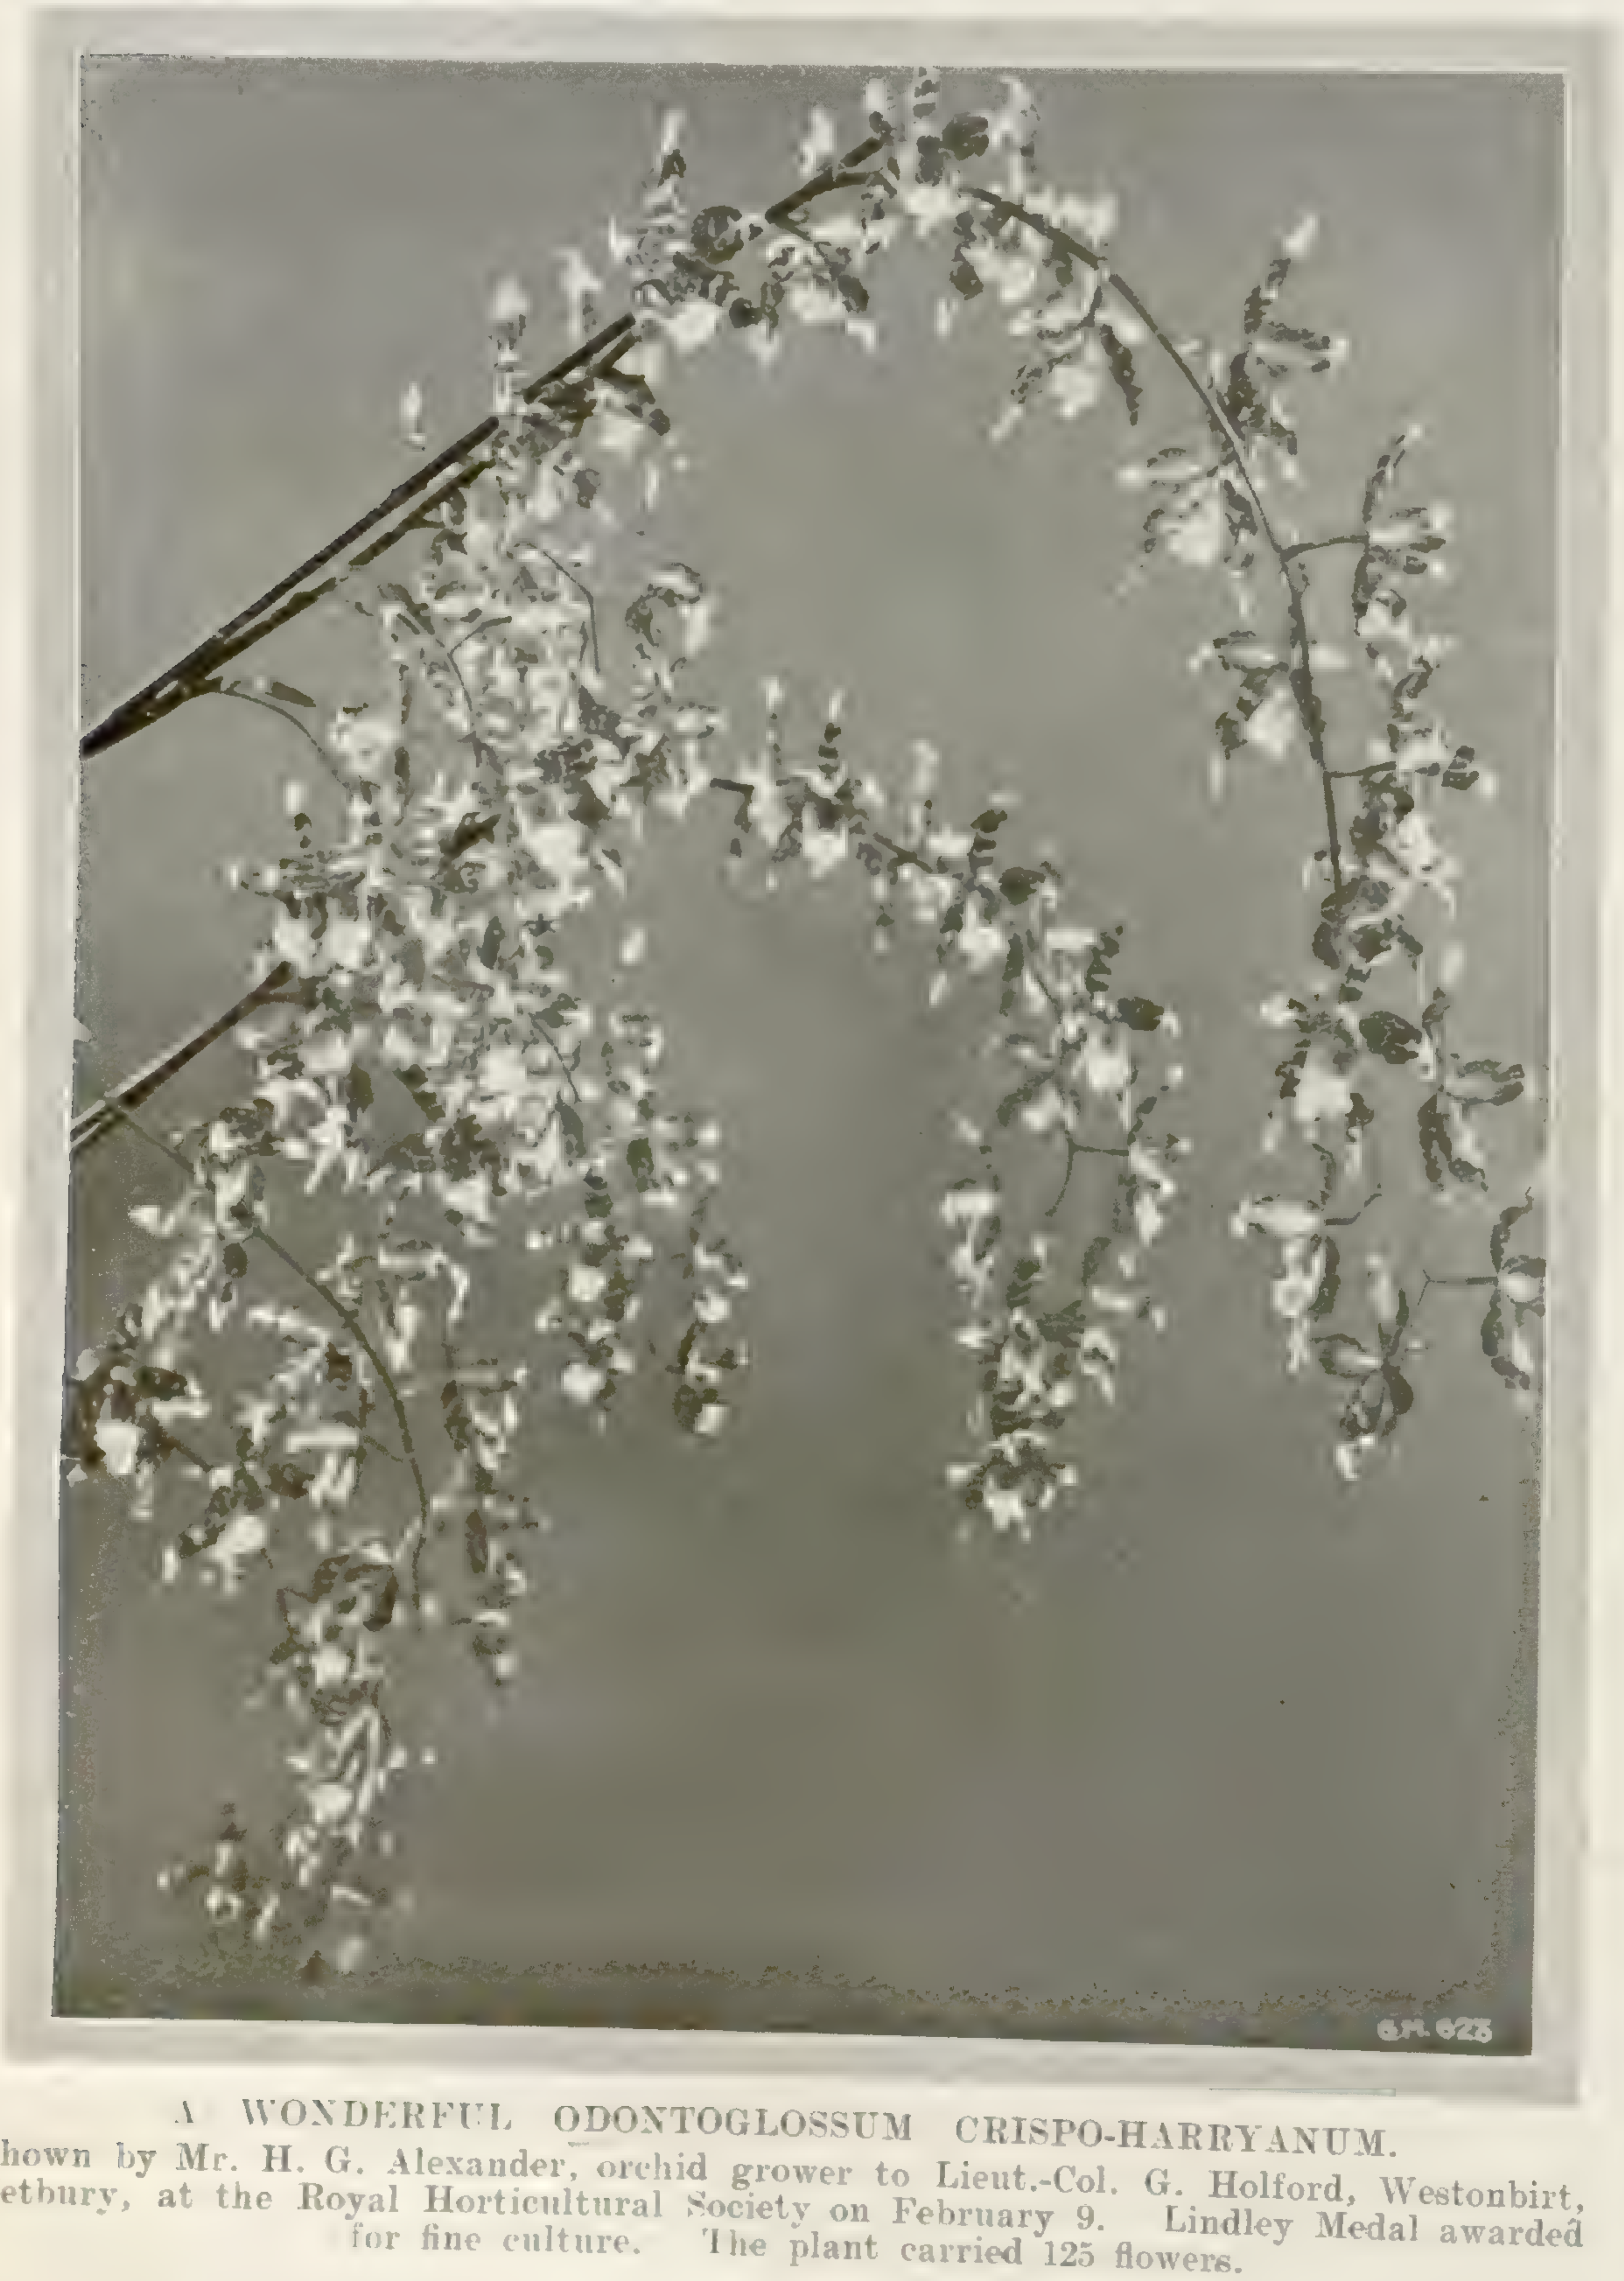
Buds may be roughly divided into two classes, successional and adventitious. It is to the former class of bud that we owe the annual renewal of arboreal foliage and the extension of tree growth generally. At the base of every leaf, at the point of its attachment to the twig, a bud is developed prior to its fall in the autumn, and it is this bud which in the spring bursts, and, according to its nature, either forms a leaf-bearing branchlet or fruit-forming flowers. This kind of bud may therefore be regarded as purely normal. Adventitious buds on the other hand generally involve transformations of cellular energy and are to that extent abnormal.

Thus with some fleshy leaves such as those of begonias, a severance of the network of veins causing a wound, will result in the formation of buds at the edges of the wound which in the ordinary course would not have been formed, and prior to the wound were not even existent in an embryo state. The leaf cells were pursuing their normal course of absorbing carbonic acid from the air and sap from the soil, and working this up by the stimulus of light into nutriment for the flowers and seed and the strengthening of the plant structure generally. The veins being severed this transference ceases, and the cells at the point of rupture being surcharged find a vent by becoming reproductive and building up a series of buds or individual plantlets with incipient roots, which only require careful treatment to become independent ones.

Such buds as these constitute a wonderful provision of Nature to secure the existence of her plant creations under adverse circumstances. To this end although in the development of a plant the cells adopt all sorts of different functions and assume, these functions fulfilled, all sorts of different forms, Nature has provided that in the initial stages of their development, or even later, the primary normal power of reproduction of the individual shall not be lost but can be reassumed in case of need. Thus in the case of all plants propagated by cuttings, although the foliage is usually eventually developed from what we have termed successional buds left to that end, the cells at the base have the faculty of budding out, not into leaves, since underground they would be useless, but into roots well fitted to supply the needful sap to the leaf buds above. It would be natural to assume that the cells at the point of severance of the cutting, far away it may be from the root system, and whose original function had been the formation of a woody stalk, would have lost the faculty of building up a root system; but it is clear that all faculties are retained in a latent form, since as we know the converse case exists in root cuttings where pieces of root, subjected to the light, proceed at once to build up a leaf system commencing as adventitious buds of the second class described.

Adventitious buds, we therefore see, are frequently generated owing to some interruption in the normal course of plant development, and a consequent deviation of energy into a fresh channel, the outlet for which is a new plant. In some cases, however, they appear as a normal character, as in viviparous species of ferns, where young plants are generated from buds on the surface of the fronds, and this peculiarity is by no means infrequent in varietal forms of species which normally bear no such buds. There is, however, a class of buds which are really buds proper, though not popularly so considered. We allude to bulbs of the tulip, which are really true successional buds, despite their size. They are developed at the base of the foliage of the preceding season, precisely on the lines of a successional bud on a flowering tree, the only differences being development on larger lines, and a consequent capacity for an independent start when the growing season begins. It is indeed justifiable to regard the very seed itself as a detached bud gifted with the power of producing both leaves and roots, and thus, like other buds of the other categories, capable of becoming a new and independent individual, if not too heavily handicapped in the struggle for existence.

C. T. Druery, F.L.S., V.M.H.



A WONDERFUL ODONTOGLOSSUM CRISPO-HARRYANUM.
Shown by Mr. H. G. Alexander, orchid grower to Lieut.-Col. G. Holford, Westonbirt, Tetbury, at the Royal Horticultural Society on February 9. Lindley Medal awarded for fine culture. The plant carried 125 flowers.

ODONTOGLOSSUM CRISPO-HARRYANUM.

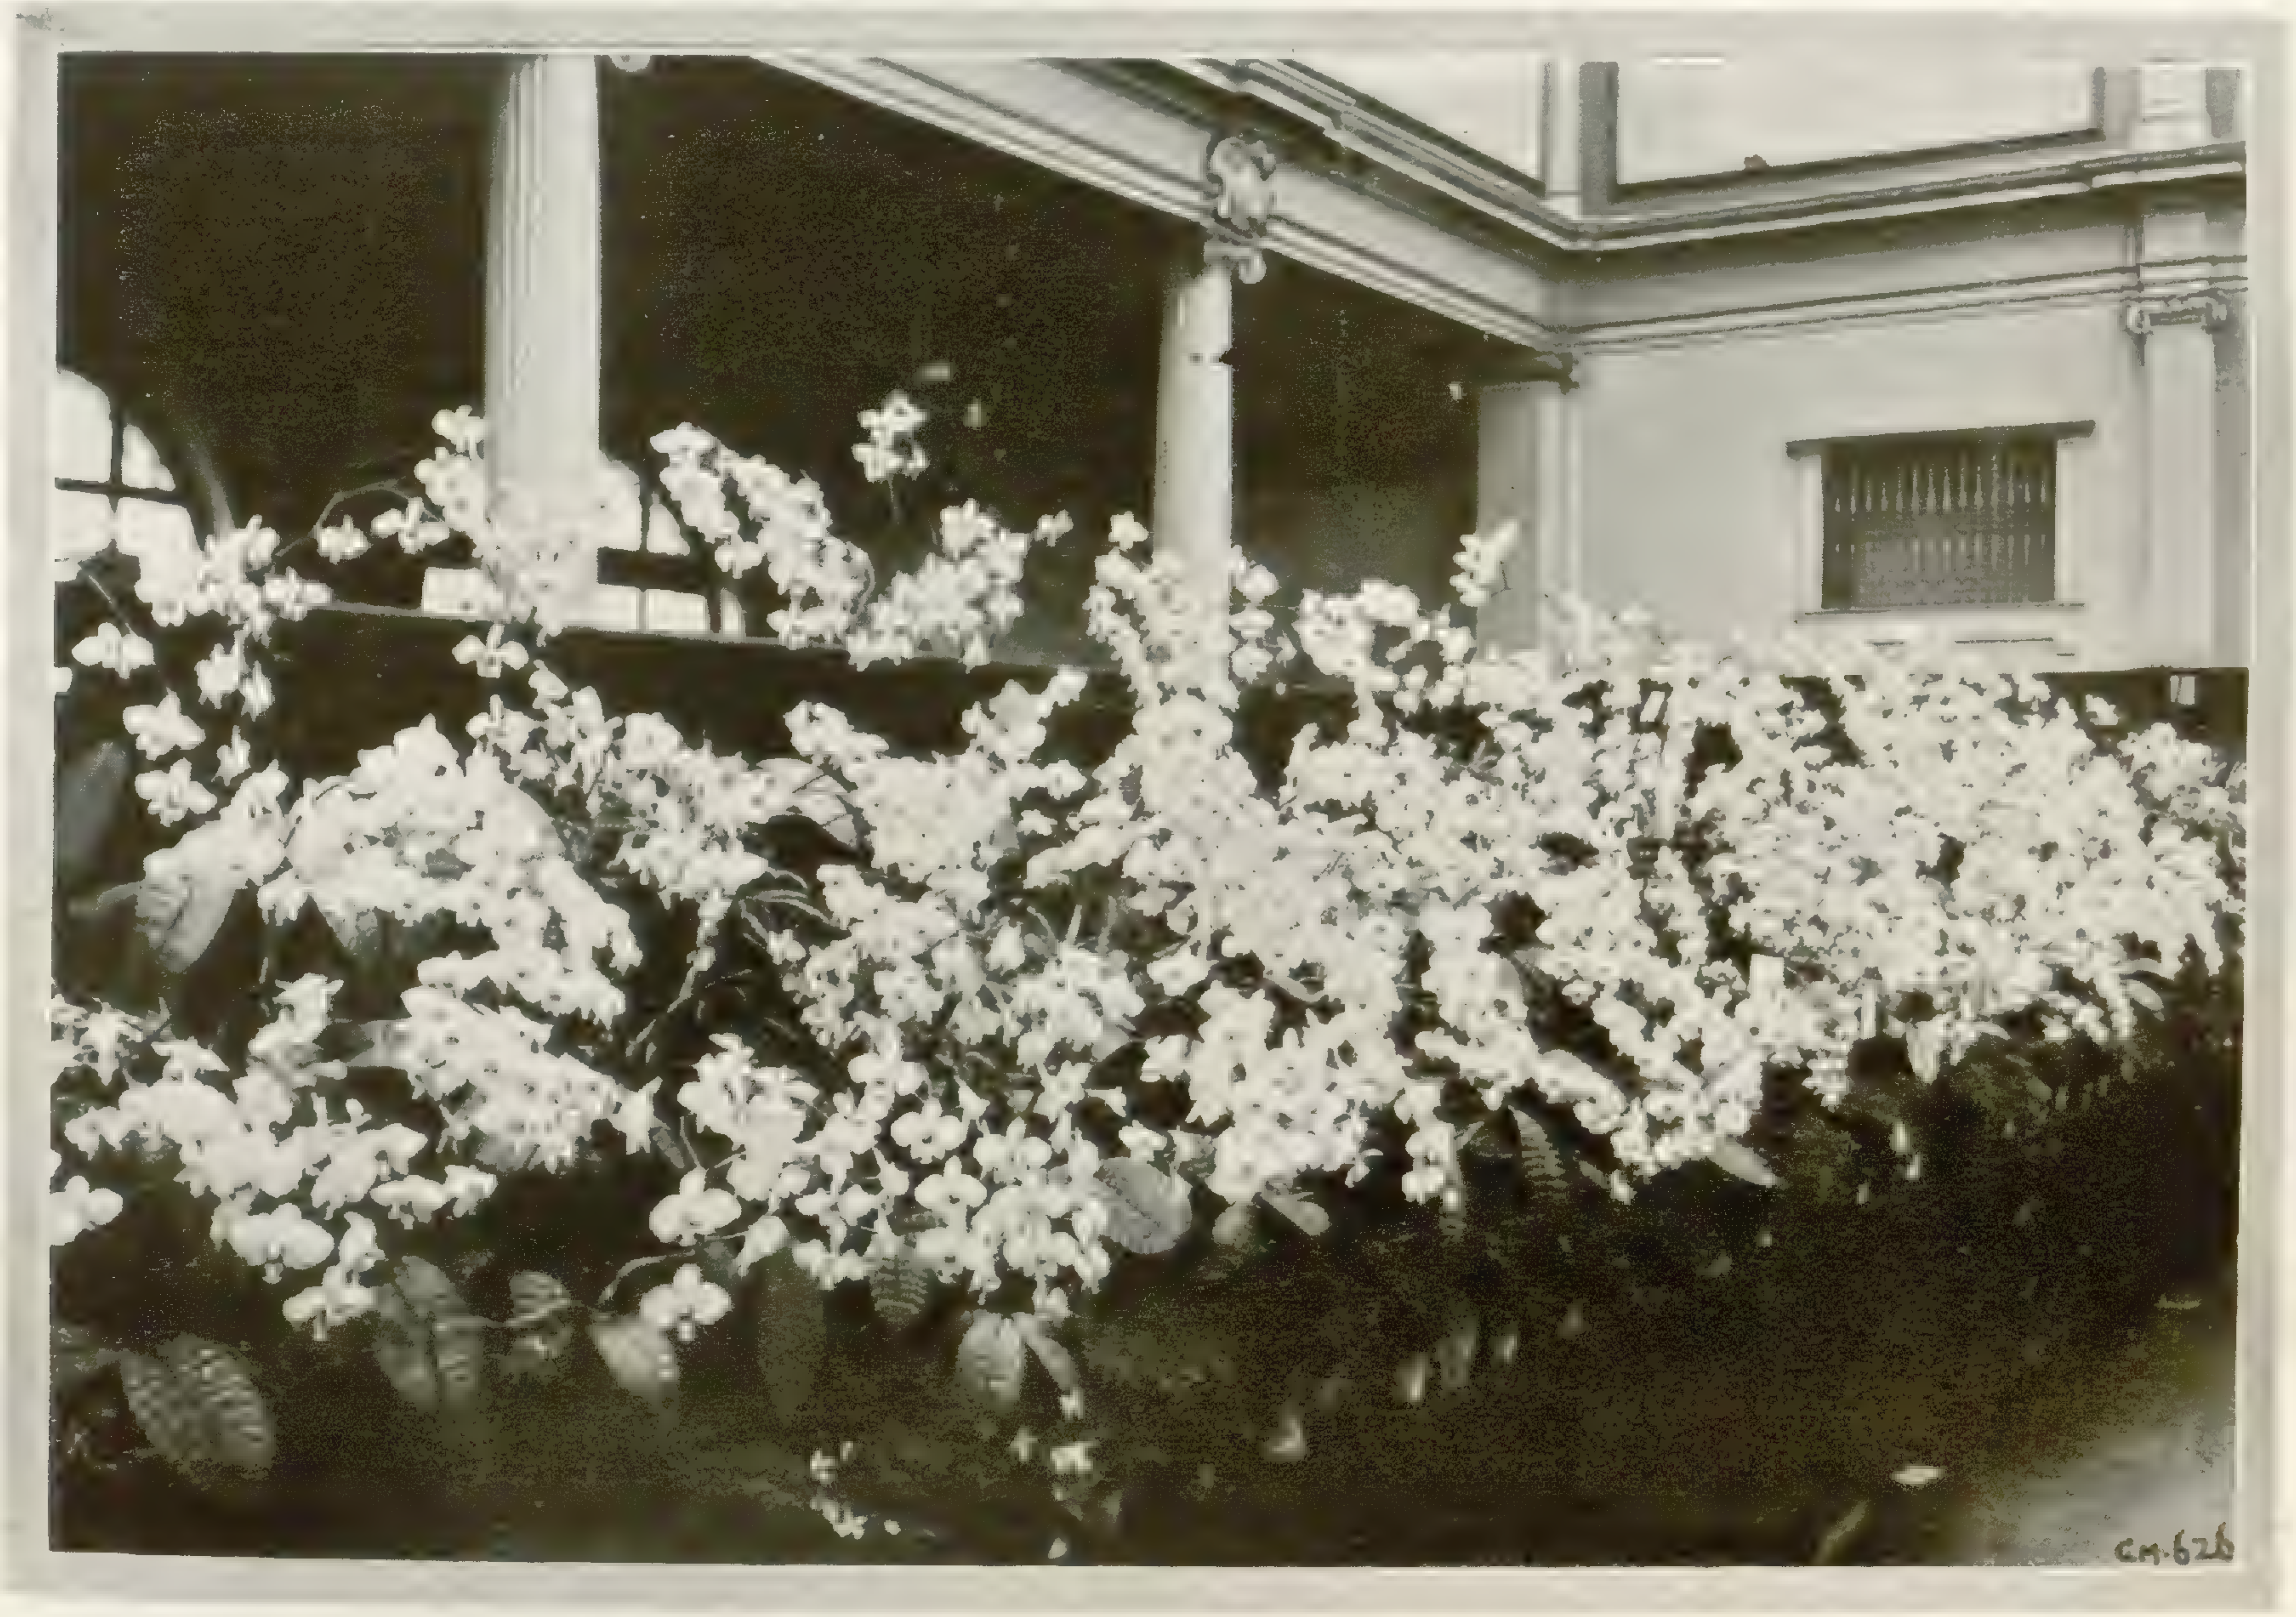
There are very many varieties of th attractive hybrid obtained by crossing th beautiful Odontoglossum crispum and th very distinct O. Harryanum, and this is not to be wondered at considering the great variableness of the first-named species, but as a rule, the plants grown and exhibited are of small size, carrying one modest spike. At Westonbirt, in Lieut.-Colonel G. Holford's wonderful collection of orchids, the plants are not cut up into the smallest pieces, but an endeavour is made to grow really fine specimens of orchids, such as Mr. William Marshall, Mr. Robert Warne Mr. Charles Webb, Mr. John Day, and Mr. Lee, used to delight the public with in years gone by. Very many of these fine specimens from Westonbirt have been figured in these columns, and we now illustrate another, of O. crispo-Harryanum, carrying four spikes and a total of 125 flowers, the largest spike bearing 65 blooms. Mr. H. G. Alexander, Lieut.-Colonel Holford's clever orchid grower, has received four or five Lindley medals, and one of these highly coveted awards was granted for this odontoglossum on February 9, by the Royal Horticultural Society. Our readers are aware, doubtless, that the Lindley medal is given for examples of unusually skilful cultivation.

BEST PLANTS FOR GREENHOUSE.—Nearly [illegible] pages are devoted to the description, propagation [illegible] culture of the best flowers and plants for the [illegible] house in The Amateur's Greenhouse, by T. W. Sanders, price 5s. net, or by post 5s. 6d., from W. H. and L. Collingridge, 148, Aldersgate Street, London.

PHALÆNOPSIS SCHILLERIANA.

It is now a little over half a century ago since Consul Schiller, of Hamburgh, introduced Phalænopsis Schilleriana from Manila, and it was in the spring of 1860 that the Consul first flowered the species in his collection at Ovelgonne, on the Elbe. The first to flower the species in this country was Mr. Robert Warner, of Broomfield, Colchester, the event occurring in February, 1862, and the plant that flowered was one of many sent home by Mons. Porte, and distributed by Mr. B. S. Williams, of Holloway. This beautiful orchid has rose-coloured flowers, but the shade of colour varies from fairly deep rose-purple to pale rose-pink, while there is also a white and an unspotted variety.

Unfortunately phalænopsis are not so extensively grown now as formerly, simply because there has been a turn of fashion, and odontoglossums and cypripediums have become popular, while it must also be remembered that hybrid orchids, notably the lælio-cattleyas, have come into being and attracted much attention. Allowing for all this, however, there is still a good deal to be said for phalænopsis, as there are few more exquisitely beautiful and graceful plants cultivated. Nowadays, given a clear atmosphere, away from towns and factories, and the necessary heat and moisture required for an East Indian orchid, P. Schilleriana offers no special cultural difficulties. Very finely grown were the beautiful plants exhibited in large numbers at the annual meeting of the Royal Horticultural Society on Tuesday, February 9, by Messrs. Charlesworth and Co., Haywards Heath. One must admire the pluck, as well as the skill of a firm that will bring a hundred fine specimens to town in such cold weather as we have been experiencing of late. The exhibit was enhanced by the presence in it of the pure white variety, P. Schilleriana vestalis. It may be safely stated that on no previous occasion has such a glorious exhibit of phalænopsis been placed before the public, and it was but fitting that the highest award, a gold medal, was granted.



A FINE DISPLAY OF PHALÆNOPSIS SCHILLERIANA.
Made before the Royal Horticultural Society on February 9, by Messrs. Charlesworth and Co., Haywards Heath.

SPRING IMPROVEMENTS IN THE GARDEN.

With the early months of a year come hosts of new ambitions and resolutions, which must be made productive of work ere long unless they are to prove useless. Few are the gardens, perhaps none, that stand in need of no improvement, while sometimes a simple introduction—pillar roses in a trio on the lawn, the opening out and carpeting of a shrubbery glade, the massing of vivid cerise phloxes against a laurel hedge, the crowning of a bank with Oriental poppies, the encircling of a pool with iris, the covering of a wall by a rose—will prove sufficient to perfect the beauty of a scene.

In a few weeks the gardener's opportunity will, in a degree, be past, for though bedding out has great possibilities, these are not to be compared in importance with the planting of roses, shrubs, and perennials.

A rapid way of turning a somewhat monotonous herbaceous border into a noteworthy one is to remove plants so as to leave a clear space of a yard, at six-yard intervals, and introduce into those openings a variety of delphiniums. There are few colours that cannot be suited by some of these stately plants. Is there a stretch of scarlet in the border? Then either pale azure blue or black-purple will tone well with it, as they will just as readily with carmine, rose-pink, lemon, white, or salmon. Royal blue delphiniums may appear against yellow, scarlet, orange, carmine, rose, or salmon, while in the dwarf Delphinium grandiflorum album we may have a white variety fit for any position, less exquisite than the tall gold-eyed white, but costing a few pence instead of shillings. If a shrubbery has become overcrowded by evergreens or shrubs which, after a short blossom season, are dull in appearance, a wonderful embellishment is the introduction here and there of pillar roses or clematises. The exact period of colourlessness should be taken into consideration, and the variety of climber selected to remedy this, as well as to tone satisfactorily with the surrounding subjects. For an example, the Crimson Rambler is probably one of the best and gayest of all roses, capable of giving marvellous loveliness in a shrubbery, but its time of blossoming is so restricted that there would be little sense in placing it where a cheering late summer and autumn effect is demanded. One of the Waltham Climbers would be a wiser choice. Clematises can be mingled up a substantial pillar, so as to obtain a succession of bloom; a variety of Jackmanni may be used with one of the patens family, or a lanuginosa with a florida.

Banks and rockeries are often lacking in attractiveness during the early summer, when spring alpines and bulbous flowers are over and the true summer ones have not begun. Groups of violas will create valuable colour patches, plants of hybrid pyrethrums can be located in places, while various achilleas prove of utmost service, thriving equally well among rocks or on exposed summits. Few are the gardens in which these cultivated yarrows are sufficiently represented; the dwarfs include the white blooming and silver leaved Achilleas ageratifolia, Kellereri, and umbellata, and the white-leaved, yellow blooming, A. sericea. Taller kinds, in white, are the popular A. ptarmica The Pearl, and the narrow foliaged Achillea mongolica; the latter is seen to perfection when allowed to trail downwards over a bank or rockery. Taller yellow kinds include Achillea filipendulina, which gives its blossom in dense heads, and reaches a height of four feet; also the effective silver-leaved Achillea clypeolata.

Rose arches across a walk quickly change a low, level garden into one of varied aspects, besides creating valuable sun and shadow effects, and helping to screen off portions of the land. Four arches of substantial make and fair width, placed where four walks join, make an arbour of great usefulness for setting chairs in during summer heat; some of the lavish leaf-making rambler roses should be chosen, with some of the perpetual blooming climbers to cover these, and the first season's canopy can be added to by the presence of plenty of annual convolvuluses and canary creeper.

Before bedding-out time the shapes of the beds should be attentively studied; in many cases alterations of outline, or increase or diminution of size, will either introduce new attractiveness or remedy old defects; in other instances, where the original schemes left nothing to be desired, it will be found that outlines have become blunted, or overaccentuated, and, therefore, the patterns are no longer mathematically correct.

Lawns that are bare need speedy planting with groups of shrubs, pillar, or standard roses, specimen trees, or clumps of grasses and herbaceous subjects; other methods of dealing with them are the erection of trellises, espaliers, arches, shelters, etc.; even mounds, tree stumps, rockeries, and urns and raised beds are to be recommended for various positions, but too free a use of ornaments must, of course, be avoided, lest the remedy prove worse than the evil.

Lastly, walls, fences, and trellises, pergolas, and arches in need of additions should be at once provided with climbers, high or low; especially where old roses, etc., have become unsightly about the roots and stems do lighter-growing companions effect remarkable improvements.

M. H.

SUPPORTS FOR ROSES.

Now that the rosery is being cleaned up ready for the approaching season, a few hints respecting suitable supports may be welcome. So far as the ordinary standards are concerned I have found no better support than a good stake, preferably of larch, oak, or chestnut, in the order named. If one can procure pitch pine sawn out in lengths, and about 2½ inches square, these are better still. They are more durable, and do not warp or sag. Iron spikes, some of them with three prongs similar to an eel spear, were much used in old rose gardens. But metal of all kinds, being so much more susceptible to atmospheric changes than wood, does not recommend itself to me when good timber can be had. Leather bands placed between the metal and rose reduces the effect of sudden change in temperature, and is also needed in any case to stay the chafing from wind swaying, which is frequently the forerunner of canker.

Hollow pipes, such as are used for gas, etc., make a capital and sound stake where cost is not so much an object, and if painted, have a neater and more stem-like appearance than a large stake.

Recently we have had a new use for standard roses in the weeping forms adopted with the strong-growing Wichuraianas and their numerous hybrids. The effect of these is greatly enhanced when the head of the plant is trained to flow over a much wider space than would be the case if allowed to droop naturally. They are being used, in short, much the same as the weeping ash and willow, carried over so that a small seat can be accommodated underneath, and they form a charming feature, with their cascades of blossom flowing almost to the ground. As this class is almost evergreen and remarkably free from rose pests and diseases, they are pleasing throughout the season. I have seen several styles of spreading out these roses, but none more effective and simple than that invented by Mr. Pinches, of Camberwell. This is a strong galvanised frame in the form of an umbrella. The shoots of the rose are drawn through this and allowed to flow over at will. It is made in complete form for young, fresh-planted trees, and in two pieces to allow of better fixing in the case of older and established plants. The great advantage is having something to secure growths to that will retain its shape and last for years. I have already had to fix several and found no difficulty. Wooden frames, if made sufficiently light in appearance, do not stand the strain long enough.

In forming a pergola for roses do not fear to make it sound, even if some of its supports are rather coarse in appearance. This adds rather than detracts from its beauty when the roses begin to grow freely, and unless we have some extra strong supports the whole structure is liable to collapse just when it is at its best, should we get strong winds. It is the same with pillars. A stout larch pole that has had its branches left on nine to twelve inches long is a good stake. Unfortunately these rot in the ground rather quickly, and it is better if they can be tarred, or "dipped" similarly to hop poles. The stumps of fruit trees make a capital support, and when set in with the bole of roots to steady them they stand exceptionally well. Where a Thuja Lobbi or similar tree has died a very pretty effect is secured by cutting off its branches fairly close to the stem and planting such roses as Dorothy Perkins, Crimson Rambler, or Felicité Perpetue against it. Here we have the best support possible.

On walls and fences we have found nothing to equal galvanised spikes with eyelet holes; fix these about three or four inches from the wall and thread strands of wire through the holes. The support is always there, and the growth much easier to secure or remove, besides avoiding the inevitable destruction caused by nailing

Uckfield. A. Piper

GALANTHUS IKARIÆ.
A very fine snowdrop, exhibited by Messrs. Barr and Sons, at R.H.S. Meeting, on the 9th inst.

GALANTHUS IKARIÆ.

This bold snowdrop is one of the best, as it is also one of the most distinct. It comes from Nikaria, and is notable for its broad glossy green recurving leaves. The plant grows about nine inches high and blooms in February, producing large snowy-white blossoms that have their inner segments heavily tipped with green, this green colouring often extending half way up the segment. This is one of the newer introductions, and is a lovely species, and, as it can now be readily obtained at a moderate price per hundred, it should soon be more frequently found in gardens. In a very pretty display of choice snowdrops made by Messrs. Barr and Sons, Covent Garden, at the Royal Horticultural Hall, Westminster, on February 9, Galanthus Ikariæ was conspicuous, and attracted a large amount of attention.

Cabbage.—The severe winds and frosts of last month have, in many cases, damaged this crop by severely checking growth. Choose a fine day, and make good any vacancies, and at the same time run the hoe between the plants, thoroughly disturbing the surface of the soil. If there is a shortage of plants sow seeds in boxes or in frames.—C. Flack.

PRIMULAS AT READING.

To those who take an active interest in horticultural pursuits it is a matter of common knowledge that for a long series of years Messrs. Sutton and Sons have devoted special attention to the development of the Chinese primula, and that in this work they have achieved so high a degree of success that their accomplishments might well be described as veritable triumphs in the art of cross-fertilisation and selective culture. General as this knowledge undoubtedly is, few who have not had an opportunity of visiting the firm's trial grounds when, as now, the Chinese primulas are in perfection, can fully realise what has been accomplished in the creation of new forms, and in the improvement of types that have been in cultivation for several years. The advances made by the firm in connection with these flowers are such as to enormously increase their usefulness for decorative purposes during the winter season, and the unique display they are now producing affords an object lesson of immense value in relation to plant development generally.

The visit made to Reading the other day was additionally interesting, from the fact that amid the thousands of plants, representing the types of the highest degree of excellence, is a plant of the wilding from China from which the present race of primulas has descended. The difference in growth, in truss, in flower, and in colour of this modest-looking plant, as compared with the most recent creations, is little short of marvellous, and it must be difficult for those who have not some knowledge of cross-fertilisation to accept without hesitation the statement that it is the progenitor of the magnificent types that are now at the command of the cultivator. In instituting a comparison between the wild type, which is here so well represented, and the finest of recent varieties, one might be excused for regarding the Chinese primulas as extremely plastic in their composition, and then be filled with admiration of the splendid work that has been accomplished at Reading; but to regard the species and its descendants as possessing more than the ordinary degree of plasticity would be to underestimate what has been accomplished. Whatever may be the degree of mobility, there is, on the one hand, a low-growing plant, with diminutive leaves and small blush-coloured flowers, with corolla lobes so narrow as to suggest the sails of a windmill. And, on the other, the modern forms, which comprise plants of robust habit, with large leaves, variable in shape and colour, and bearing in large trusses flowers of superb form, and ranging from pure white to royal purple, in one direction, and to deep crimson in the other.

With the present state of the knowledge of plant development it is not difficult to understand how the small, slightly-lobed leaves of the species have been amplified, deeply cut, and, in some cases, so elongated and finely divided as to obtain for them the designation of fern-leaved. But when the attention is turned to the colouration, well might it be asked whence have been derived these shades of pink, rose, salmon purple, crimson, lavender, deep blue, and scarlet? There has been no intervention of other species in their production, for up to the present time the species and its descendants have refused to consort with other members of the primrose family. These remarkable results in colour development have been obtained by cross-fertilisation and selective culture, and if impossible to say by what process the rearrangement of the colouring matter contained in the sap has been effected, it can be said that in the process of improvement the several breaks in colour have been taken full advantage of in the development of new hues.

We have from time to time made reference to the experimental side of primula culture at Reading, and, in our reference thereto have described how long a period usually elapses between obtaining a new break in colour or form, and raising it to the high standard essential before distribution. We have also pointed out that sometimes, when the desired form and colour have been obtained, it has not been found possible to so fix the type as to admit of it being sold separately. Two of the houses are being utilised in the demonstration of the Mendelian laws in their relation to these flowers, and they contain so much of interest that it is with considerable regret we are unable to do more than make this brief reference.

Five distinct types of the Chinese primula are grown by Messrs. Sutton and Sons, and these are the single-flowered, the single-flowered fern-leaved, the giant single-flowered, the double, and the stellatas, and in each type a wide range of colours is represented. Prominent in the first of the sections is The Duchess, remarkable for its broad zone of bright rose-carmine surrounding the yellow eye, and one of the most distinct and beautiful primulas in the section. Brilliant King, a highly effective variety in the way of Crimson King, but the rich crimson flowers are larger and more finely fringed. Lord Roberts resembles the last-named in habit, but the flowers are rich salmon-pink, and borne in bold trusses above the dark leaves, to which they present a pleasing contrast. Coral Pink has flowers of a lighter hue than those of Lord Roberts, the colour being aptly described as coral-pink, and very pleasing. Reading Pink and Brilliant Rose are two excellent varieties, with finely-formed flowers of the colours indicated by their names; Pearl, a white form of great excellence, introduced by the firm about thirty years ago, still occupies a prominent position amongst the white varieties, and enjoys a high degree of popularity for conservatory decoration by reason of its robust habit, easy culture, and effectiveness. Royal White is a robust variety of the highest quality, and the large bouquets of pure white flowers, set in bronzy-green foliage, are singularly effective; it is indeed so distinct and attractive as to merit widely-extended culture. Reading Blue and The Czar are two exceptionally fine blue varieties, the flowers of the first-named being bright blue, and those of the second are dark blue, differing but little from the colour of the violet of the same name.

CHINESE PRIMULA IMPROVED DOUBLE SCARLET.
Raised by Messrs. Sutton and Sons.

The fern-leaved varieties have been brought to a high degree of perfection within recent years, and of these the following made a strong appeal to us, namely, Purity, a remarkably fine pure white variety, bearing flowers of the largest size and superb form, and having bronzy foliage. Improved White, a superb form, with bright deep green leaves; Rose Pink, a lovely pink variety; Blue Fern-leaved, a charming variety with large, finely-formed flowers, similar in colour to Reading Blue; Lavender has lavender-blue flowers, and presents a pleasing appearance, whether associated with other classes of plants or arranged in bold blocks, as at Reading. Double-flowered primulas have much to recommend them to the notice of cultivators, for while of quite exceptional value for decorative purposes, their flowers can be successfully utilised in a cut state. Of outstanding merit in this section is the Improved Double Scarlet, to the development of which Messrs. Sutton and Sons have devoted much attention for many years past. In its present form it as nearly approaches the ideal as one can hope to see; the habit is perfect, and the bold trusses of brilliant crimson-scarlet flowers, rising above the leaves, are very effective. The Duchess in its double form is of interest, as evidence of the value of persistent endeavour conducted along well-devised lines, and it is immensely attractive. Pink Beauty is a charming variety, with finely formed flowers, exquisitely coloured pink. Double Salmon Pink, Double Blue, and Double White are three beautiful forms that are quite indispensable, and Carnation-flaked, which has pearly-white flowers splashed with crimson, and Double Alba magnifica, remarkable for its moss-curled leaves, are also desirable, by reason of their distinctness.

The giant section which Messrs. Sutton and Sons have been successful in developing constitutes a notable and highly attractive feature in the magnificent display of primulas now at its zenith at Reading, and the noble proportions of the plants, the large size, and superb form and finish of the flowers, and the glorious colouring, would more than suffice to justify a long journey for the purpose of enjoying their distinctive charms. As here extensively grown for seed production the great array of plants impress one by their effectiveness, and it is not difficult to imagine the attractions of large specimens grown for conservatory decorations. Giant Royal White and Giant White are two fine forms, differing in the colour of the leaves, which are bronze-green and bright green respectively. Giant Pink is simply invaluable for decorations, the bold trusses of large carmine-pink flowers being exceptionally effective. Very fine also are Improved Giant Crimson, its colour indicated by its name, and Giant Salmon Pink, a beautiful variety, with flowers of the colour known as terra-cotta.

As in the case of the other sections, an immense amount of excellent work has been accomplished in the improvement of the stellate, or star primulas, which have of late years attained to a high degree of popularity. To particularise is not now possible, but it must be mentioned that the collection includes twelve or more varieties of a high order of merit.

MENDELISM AS APPLIED TO SWEET PEAS.

(Concluded from page 132.)

Let me give a few illustrations copied from my own notes of work actually done:

King Edward x Dorothy Eckford.—First generation, rose-coloured flowers. Second generation, three-quarters good reds, one quarter good whites.

Dorothy Eckford x King Edward.—Gives the same result as above.

Jessie Cuthbertson x Lady G. Hamilton.—First generation, rather poor, pale blue flowers. Second generation, three-fourths or more lavender and blue shades, remainder resembling Jessie Cuthbertson, Jeannie Gordon, and a few blue striped flowers resembling Princess of Wales. In the first generation seed was round, in the second generation it was mixed round and wrinkled, as was to be expected with Lady Grizel Hamilton as one of the parents.

Scarlet Gem x King Edward.—First generation, red. Second generation, all red—quite true red, mostly Scarlet Gem type.

Dorothy Eckford x Jessie Cuthbertson.—First generation, unfixed-looking flowers. Second generation, half light-striped flowers, half white.

Mrs. Collier (white seed) x Dora Breadmore (black seed).—First generation, cream-coloured flowers, black seed. Second generation, cream flowers and flowers resembling Dora Breadmore, and a few pinks, seed black and white. Third generation, similar to second.

Mrs. Collier (white seed) x Miss Philbrick (mottled seed).—First generation, flowers like Romolo Piazzani in colour, seed mostly wrinkled. Second generation, primrose white, blue and mauve flowers, seeds black, white, and wrinkled.

These observations are made from long rows of plants, some of them 300 feet long, and the proportions are carefully studied, but not counted. When I say that we frequently get several ounces of seed from a single plant in F 1 generation it will be understood that we cannot afford the time to count up and tabulate the individual plants.

To speak of another single pair of characters which "Mendelize," I may mention Spencer and plain standards. If Countess Spencer is crossed with King Edward, or any fixed hooded or plain standard variety, the Spencer form is lost in the first generation, but it recurs in the second in the proportion already referred to. To give an illustration of di-hybridism, where two pairs of characters are concerned, let me refer to the working out of the cross just referred to, Countess Spencer x King Edward. This cross was made with the object of obtaining a crimson Spencer-shaped flower, and it was successful. In F 1, as already stated, the plants gave plain standards and were of a rather poor red colour. In F 2 were found plain reds, plain pinks, true Countess Spencer and waved crimson, the two latter in very small proportion. I cannot give figures for the reason already stated, and it must be remembered that when sowing large batches outside, a number of plants always perish from various causes. It is of importance to say that the true waved reds bred true. Another cross made in 1906 was Countess Spencer x Mrs. Collier. In 1907 the plants yielded flowers with plain standards only and of a pink colour. In 1908 the result was a large proportion of plain pinks and plain creams with a very small percentage of true Countess Spencer and true Primrose Spencer. In 1909, I have no doubt the latter will breed absolutely true.

Some years ago, when visiting the University Experimental Farm at Cambridge, I had pointed out to me the remarkable discovery which had been made by Mr. Bateson and his collaborators. Emily Henderson sweet pea was found to produce two kinds of plants, differing in the shape or structure of their pollen. Some plants produced only round pollen grains, others produced elongated pollen grains. Being self fertilised, like all other sweet peas, these plants bred true to these characteristics, but on being crossed, the round-pollen plants with the long-pollen plants, a wonderful, and I am sure a quite unexpected, result was found. In the first generation the plants had purple coloured flowers with long pollen, which was supposed to be a reversion to a former ancestral type. These plants were self pollinated, and in F 2 generation Purple Invincible, Picotee-edged, Painted Lady, tinged white, and white flowers were found. Whence arose all these colours, or varieties as seedsmen would call them? Latent determinating factors must have been present, or absent, in one or both kinds of Emily Henderson, and until they met in the way they did colour could not be developed. Emily Henderson, therefore, as we all knew it was only pure for whiteness, and only so for as long as the two kinds (differentiated only microscopically by the shape of their pollen grains) were continuously selfed.

Space will not permit my describing at length the deeply interesting process by which the characters are carried through the different generations in absolute purity. According to Mendelism there is rarely fusion or blending—there is re-arrangement, which means novelties to the seedsman. Let me quote a few lines from Lock's work on "Variation, Heredity, and Evolution." "Both a pair of structural characters and a pair of colour characters can Mendelize, that is to say the germinal representatives of such pairs of characters remain perfectly distinct in the hybrid plant, and separate completely at the formation of its gametes (germ cells) in such a way that an equal number of gametes arises containing either character. When a pair of gametes fuse together in the process of fertilisation the resulting cell is known as a zygote." From the zygote the adult plant is developed, and it of course follows if the gametes which formed the zygote were both pure, the plant will be pure—a homozygote. If they were different, i.e., if each gamete carried a different character the plant will not be pure, but a heterozygote.

In concluding this brief paper I can only refer to one other of Mendel's experiments, but as it proves so much I wish to state it fully. It was undertaken to prove that among the progeny of the crosses, constant forms appear in all combinations of the associated characters. Quoting from Mendel's paper in the "Royal Horticultural Society's Journal":—"In the following trial the characters of floral colour and length of stem were experimented upon, and selections so made that in the third trial year each character ought to appear in half of all the plants if the above theory were correct. A, B, a, b serve as indicating the various characters.

A.—Violet-red flowers. a.—White flowers.
B.—Axis, long. b.—Axis, short.

The form Ab was fertilised with ab, which produced the hybrid Aab. Furthermore aB was also fertilised with ab, whence the hybrid aBb. In the second year, for further fertilisation, the hybrid Aab was used as seed parent, and hybrid aBb as pollen parent."

$$\overbrace{\text{Violet flower}}^{A}\text{ with }\overbrace{\text{short axis}}^{b}$$

crossed with

$$\overbrace{\text{White flower}}^{a}\text{ with }\overbrace{\text{short axis}}^{b}$$

resulting hybrid contained
Violet, white, short axis
=A a b
This Mendel made the female parent, the possible egg cells of same being represented by
A b a b

$$\overbrace{\text{White flower}}^{a}\text{ with }\overbrace{\text{long axis}}^{B}$$

crossed with

$$\overbrace{\text{White flower}}^{a}\text{ with }\overbrace{\text{short axis}}^{b}$$

resulting hybrid contained
White, long axis, short axis
= a B b
This Mendel made the pollen parent, the possible pollen cells being represented by
a B a b

From the fertilisation between the possible egg and pollen cells four combinations should result:—

(1) AaBb. (2) aBb. (3) Aab. (4) ab."

Mendel argued that if his theory was correct, in the third year, out of all the plants:—

*The half should have violet flowers (Aa), Classes 1, 3.

The half should have white flowers (a), Classes 2, 4.

The half should have a long axis (Bb), Classes 1, 2.

The half should have a short axis (b), Classes 3, 4.

From forty-five fertilisations of the second year 187 seeds resulted, of which only 166 reached the flowering stage in the third year. Among these the separate classes appeared in the numbers following:—

Class.	Colour of Flower.	Stem.	
1.	Violet	long	47 times.
2.	White	long	40 times.
3.	Violet	short	38 times.
4.	White	short	41 times.

There consequently appeared:—
The violet flower colour (Aa) in 85 plants.
The white flower colour (a) in 81 plants.
The long stem (Bb) in 87 plants
The short stem (b) in 79 plants.

Mendel confirmed the theory adduced not by means of this experiment alone, but by others on similar lines dealing with different characters. In the words of Lock, "the first great debt that Science owes to Mendel is the demonstration that there exist definite and separate unit characters." That these characters can be separated and built up again in new combinations opens up a bright vista of interesting work to the careful seed-grower and florist. He can create, under definite laws, fresh forms of beauty to delight the eye and satisfy the mind of his patrons. If I may give a word of advice it would be this—keep a record of work done. Such is always interesting and may some day prove very valuable.

Arabis serrata.—One of the rarer arabises which will probably be seen in flower in this country this spring is Arabis serrata. This is a little-known Japanese species, of very close-growing habit, and having small leaves in dense rosettes. The flowers are snow white, and, if equal to the descriptions given, it will be a plant which will be an acquisition to rockeries. It comes from the mountains of Japan, and should be quite hardy with us.—S. Arnott.

---

* To make this quite clear I may remind [illegible] that violet is always dominant over white, and [illegible] could only be produced when ovules or eggs [illegible] the white factor met pollen cells carrying [illegible] factor.

THE ASPENS.

Two species of populus are usually spoken of under the name of aspen, one, the "Common Aspen," being scientifically known as P. tremula, and the other, P. tremuloides, being know under the common name of "American Aspen." The principal peculiarity of both trees is centred in the long, delicate, curiously flattened leaf-stalks, which, from their formation cause the leaves to be continually on the move even on the calmest day. They have, however, further recommendations to commend them for general attention, for, in addition to forming handsome trees, the male inflorescences are of imposing appearance, and are produced with such freedom as to almost hide the branches. Like other poplars, both trees succeed best in moist ground, and are specially adapted for the banks of lakes or streams or for planting in wet and marshy places. Like most other members of the family they may be increased by means of cuttings of ripened wood a foot or so long inserted out-of-doors during winter. They may also be propagated by means of suckers, whilst the varieties may be grafted on stocks of the respective types. The well-marked varieties are few in number, and the most prominent are mentioned below.

The Common Aspen.

P. tremula is widely distributed through the cooler parts of Asia, Africa, and Europe, and is found wild in the British Isles. Under suitable conditions, it attains a height of 70 or 80 feet, with a considerable girth, but it is frequently met with in a much smaller state. The bark is grey, and the leaves cordate or rounded, with evenly serrate or toothed margins. The inflorescences are borne during March or sometimes in early April, and they are in the form of catkins, the male ones being specially noticeable, as they are 3 to 4 inches in length, of a greyish or light brown colour, and silky appearance. The principal varieties are:

P. t. pendula, the "Weeping Aspen," an ornamental tree, with weeping branches, suitable for planting on a lawn where the conditions are favourable, or for placing on the margin of a lake. It is usually increased by grafting on to tall stocks of the type.

P. t. purpurea.—This differs from the type on account of the leaves being of a purplish colour.

P. t. villosa is distinguished by the woolly character of the leaf surface.

As with many other common trees, a great many legends and superstitions centre round the aspen. The peculiar sensitiveness of the leaves has given rise to most of these legends, and the majority of them purport to supply the reason for the almost constant motion of the foliage. The aspen also shares the questionable honour of having supplied the wood which formed the cross on which Christ was crucified, and for this reason, one legend states, the leaves have never, since that date, been still until they have fallen from the tree. Another legend avers that at the time of the crucifixion all trees were horror-stricken, and made public lamentation with the exception of the aspen, which held itself upright, cold and arrogant, refusing to lament. For a punishment it was suddenly struck with a trembling fit, and from that day forth it was condemned to tremble in all its limbs even when there was no wind and other trees were at rest.

In striking contrast to the pride of the aspen, some other trees are said to have voluntarily given themselves up to mourning for the remainder of their lives. The yew is credited with saying, "I will be the guardian of graveyards. No bee shall rob my poisoned flowers with impunity. No bird shall rest on my branches; for my exhalations shall give forth death." The cypress said, "I will be the guest of tombs and the testimony of grief." Not to be outdone by the others, the pine said, "As a sign of mourning, from this day forth my foliage will remain sombre, and I will dwell in solitary places."

Another legend attributes the shaking of the leaves to a rebuke for the arrogance of the aspen on another occasion. This was when the Holy Family was fleeing into Egypt. At one period they are stated to have entered a forest, and all the trees bowed to the earth in adoration with the exception of the aspen, which stood proud and erect. As a punishment it was condemned to perpetual unrest. The following lines, taken from "Plant Lore," allude to the last-mentioned legend:

"Once our Saviour walked with men below,
His path of mercy through a forest lay;
And mark how all the drooping branches show,
What homage but a single tree may pay!
Only the aspen stands erect and free,
Scorning to join the voiceless worship pure;
But, see! He casts one look upon the tree,
Struck to the heart she trembles evermore."

It is probably on account of these legends that the aspen has been accepted in some countries as the "Tree of Liberty." It chose to stand alone, and for that reason revolutionists have accepted it as their badge. A legend which is rather unchivalrous and uncomplimentary to the fair sex, states that the aspen was made from women's tongues, and it is therefore impossible for the leaves to keep still.

The American Aspen.

P. tremuloides forms a somewhat smaller tree than P. tremula, though there are many points of resemblance between the two trees. The leaves are cordate and very similar in shape, except that they are often somewhat pointed. It is widely distributed in N. America, and occupies a similar position there to what the common aspen does in Europe. Like the common aspen it possesses a pendulous variety, which is of considerable decorative value.

W. Dallimore.

CHICORY.

Although a native plant, the chicory is not cultivated nearly as much as it deserves to be in this country. I am here referring to it both as a vegetable for cooking purposes, and when grown and blanched for use during the winter, for salad. It is one of the easiest possible plants to cultivate, as it will grow successfully in any soil, and on any site. It is perfectly hardy, and it can be brought forward for use for the salad bowl in a very short time during six months out of the twelve.

Chicory is imported in very large quantities from France and other countries, and good prices are realised, but I must confess it arrives in not nearly such good condition as that in which it can be grown at our very doors, and brought to perfection by any cottager. The very best varieties only should be grown, as these are vast improvements on the old forms. I have for some years grown a variety sent out by Messrs. Sutton and Sons, called Christmas Salad, a splendid type and always true to character. Two or three sowings should be made during April and May on well trenched ground.

Sow in rows one foot apart and thin the seedlings to nine inches apart when large enough, then, except for hoeing to keep down weeds, and to promote growth, no other attention will be required until the time of lifting. A few plants may be lifted as required and placed in the darkest corner of the mushroom house or in a cellar, trimming off the old leaves to within two inches of the crown. During the autumn, before it has died down, and during mid-winter, or when frost is likely to occur, sufficient roots should be lifted and stored in sand or ashes for use as desired. When salads have to be provided the winter through, and lettuce and endive are none too plentiful, chicory will be found of great service.

WORK FOR THE WEEK.

◆

THE ORCHID HOUSES.

ONCIDIUM MARSHALLIANUM.—This is one of the most useful of oncidiums, but, unfortunately, it is not one of the easiest to keep vigorous for many years after it has been imported. There can be no doubt that to the free-flowering characteristics of the plants may be attributed their rapid deterioration. When first imported the plants are easily induced to produce growths equally as large as those found on the imported plants. The flower spikes often carry from 50 to 100 flowers, and these, making such an attractive display, are exceedingly useful for exhibition and decorative purposes. One is naturally inclined to permit the flower scapes to remain on the plants some time, with the result that the strain thus imposed results in the shrivelling of the pseudo-bulbs, and consequently future growth of the plants is affected.

IMPORTED PLANTS usually reach this country about the present season of the year, and the earlier importations should be secured for preference. Not being so much sought after as many of the more fashionable orchids, they are procurable at a reasonable outlay. When imported plants are secured they should be carefully cleaned of all dead and decaying matter about the pseudo-bulbs and rhizomes, and especial care should be taken to see that they are not infested with undesirable insect pests. I have seen imported plants literally smothered with mealy bug that has secreted itself among the decaying matter and axils of the leaves, etc. Should infested plants be found they should either be destroyed or isolated, and kept under close observation. Plants with large pseudo-bulbs, like O. Marshallianum, are by no means the easiest to deal with when potting. It is not a bad plan to fix two or three pieces of teak wood in a pot or basket, and then fix the plant on to the wood in the same manner as if fixing them on a raft, and after giving ample drainage, fill in the surface, and as far up as practical, immediately behind the rhizome, with a potting compost of about equal portions of fibrous peat and chopped sphagnum moss. A few broken oak or beech leaves may be added to the compost if desired. These oncidiums are best grown in a warm intermediate temperature, where they may have all the available light and a humid atmosphere during the season of active growth. When growth is completed, and the plants have entered their dormant stage, it will be to their advantage to be transferred to the odontoglossum house until they show signs of renewed vitality, when they should be again transferred to the warmer house. I would advocate the plants being grown suspended from the roof in all cases, so that they may derive all the benefits afforded by this position. During the growing season the plants may be freely syringed overhead once or twice a day, and every care should be observed to see that they do not remain for a prolonged period in a dry state about the roots.—H. J. Chapman, Oakwood Gardens.

FRUITS UNDER GLASS.

THE EARLY VINES will now be making good progress, and it will be seen now which bunches should be left, therefore the process of disbudding may be proceeded with. The best-placed shoots should have some advantage, as there is always some difficulty at this season in getting a badly-placed shoot down; at the same time, if the rods and wires are far enough away from the glass, the weight of the bunch will gradually bring the lateral into position. Do not leave more than two growths to one spur, and do not leave more than one bunch to a shoot. Do not try to bring the shoots into position all at once or they will break. If any mealy bug was present last season (no matter how well the vines have been cleansed), look out for the pest two or three times a week, as it is only by extreme diligence and perseverance that it can be got rid of. Keep the floors, staging, and walls well syringed twice daily, or more often if necessary, and increase the temperature to 65 degrees. If any plants are being forced in the house endeavour to take them out as soon as possible so that the vines can have every attention.

PEACHES AND NECTARINES.—If the flowers have all set give the borders a thorough watering and raise the temperature from 55 to 60 degrees, admitting a little air on all fine days, but if the flowers have not all set continue to deal with them as advised in the last calendar. A second house should now be closed, taking care that it is scrupulously clean. If the borders are at all dry give a thorough soaking, bearing in mind that when Nature opens the flowers on the peach wall outside the borders are moist. If the house be kept closed with a little warmth in the pipes when the outside temperature is near freezing point, the buds will soon start. Syringe the trees twice daily in fine weather.

MELONS.—These will now be sufficiently advanced to be planted out, and a slight hotbed should be prepared for them in the forcing house, where a genial bottom heat of about 80 to 85 degrees can be maintained, with a top heat of 65 to 70 degrees. Some prefer to fruit the early crop in pots, but I like a narrow border, in which the plants can be placed. Soil is of some importance, and this should be of the best, more especially for the early crop. Planting needs special care. If put in too deeply the stems are apt to decay at the collar. Make the soil quite firm. A depth of six inches is quite sufficient soil to grow melons in. A sowing for a succession should now be made, placing one seed in the centre of a small pot, and affording bottom heat. A small frame inside a forcing house is a capital place to raise melons and cucumbers in.

CUCUMBERS will now be ready to be put out similarly to melons, but the soil will require to be somewhat richer. As these are gross feeders mix some bonemeal with the soil, and a little soot and spent mushroom manure also. Put a small stake to each plant to train it to the trellis, and plant out two feet apart. Sutton's Everyday comes into bearing very quickly. Old plants becoming exhausted may have a topdressing of manure to help them over the next month, when they can be rooted out.

TOMATOES.—Those still fruiting must receive every encouragement, and be afforded liquid manure at every other watering. Young plants should be shifted into 48-sized pots, and be grown on in a position near the glass, where they will soon make sturdy specimens. Another small sowing of Sunrise should be made, this variety being quick in bearing, and the fruits of a nice size and good flavour. Prick out when the seedlings are large enough to conveniently handle. A temperature of about 60 degrees suits tomatoes very well; hotter than this causes them to draw, and become weak.—W. A. Cook, Leonardslee Gardens, Horsham, Sussex.

THE KITCHEN GARDEN.

CELERY.—To provide the earliest plants of this vegetable make a sowing of seed in boxes in fine rich soil, and place it in an intermediate temperature. Germination will be aided by placing a slate or board over the box to exclude light and dry air. When the young plants show themselves remove the covering by degrees to inure them to exposure in a light and cooler position. Early plants are very subject to bolt to seed, and it is best to defer the main sowing to a later date.

BRUSSELS SPROUTS.—Where these are in early demand a sowing of seed may be made in boxes, or in a frame. Grow the young plants with as little artificial heat as possible by admitting air to the frame as liberally as the weather will permit without giving check to growth, thus avoiding a thin and weakly foliage. When the plants are large enough prick them out at from five to six inches apart in other frames, in turfy loam mixed with rough leaf-mould. From this they will lift with a satisfactory amount of roots when transferred to their outside quarters.

PARSNIPS.—As soon as the ground is in a sufficiently dry condition to form a suitable seed bed the main crop of seed may be sown. Select a calm, dry day, and lightly fork over the surface of the bed early, and allow it to remain for a time exposed to the air, afterwards working it with iron rakes to the desired fineness. The rows should be from 15 to 18 inches apart, and the drills drawn out to receive the seed should be about two inches deep.

JERUSALEM ARTICHOKES.—The first opportunity should be taken to plant the tubers of this crop. Years ago these were often placed in out of the way corners and lifted as required, but each season there appears to be a greater call for this vegetable, which consequently needs higher cultivation. No crop pays better for a deep rich soil than the artichoke, and it ought to be planted in an open and favourable site in thoroughly prepared land, with room for the development of its growth, which means from 2 feet 6 inches to 3 feet apart.

ESCHALOTS.—The main crop of these should be planted now at about 12 inches apart from row to row, and 10 inches apart in the row. It is not so necessary, in most cases, to obtain large specimens of these, as it is to have ripeness. Select a high and warm position to secure this, but care will be needed in a time of extreme drought that the crop does not mature prematurely. Give the plants assistance by providing water, and a dressing of manure if they seem to show distress.

PARSLEY.—Make a sowing of this herb in the warmest position that can be found, such as a narrow border under a south wall. Invariably I find transplanted plants do better than those allowed to remain where sown, especially in soils troubled with wireworm. In this case charge the land with soot, and transplant as soon as the plants are large enough to prick out. Should the winter have very severely damaged the old crop, and caused a scarcity, make sowings in boxes, and place them in slight heat under glass. After the young plants are well up prick them out and give the protection of a rough frame until the weather is genial enough for them to be exposed.

GENERAL REMARKS.—The stock of pea sticks will soon have to be obtained, and will find employment for the outside hands, should the weather be bad, in preparing them for use, and selecting them into lengths for the different varieties. Take every advantage of time in securing labels, stakes and other sundries in readiness for the rapidly advancing season of planting and sowing.—Charles Flack, Cholmondeley Castle Gardens.

Iris fœtidissima.—This is a native British plant, being fairly common in the West and South-west of England. It is one of the most evil-smelling plants often met with, if bruised, but a well-grown clump has some beauty of its own, though its dull purple flowers are insignificant. It is for the open pods of coral-red berries, which last all the winter, that it is appreciated, and for the sake of these it is well worth growing where one has any semi-wild place in the garden to fill. These pods should be picked just when they are beginning to burst at the point, and should be hung with the stalk upwards until they are dry, when the three sections of the pod will open widely and display the berries within. A recommendation of the plant is that it will grow in any wet and shady place, and may be left for years without being disturbed, during which it will form dense clumps three feet through, though it will not produce so many pods, proportionately, as in smaller clumps.—Alger Petts.

There is no better guide to the kitchen garden than Vegetables and Their Cultivation, by T. W. Sanders. It is a complete treatise on the general management of the garden, and the successful culture of vegetables, saladings, and herbs for home use. Price 5s. net, by post, in box, 5s. 6d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

Perpetual Flowering Carnation Society.

The annual meeting of this useful society was held at four o'clock on Wednesday, February 10, at the Hotel Winsdor. Mr. J. S. Brunton occupied the chair, and there were about twenty-five members present.

The minutes of the previous annual meeting, together with other formal matters, were proceeded with, and then the report, of which we give an abstract, and balance-sheet were taken as read.

At the annual general meeting in 1908 the title of the society was altered from "The Winter-flowering Carnation Society" to "The Perpetual Flowering Carnation Society."

A scheme for the registration of the names of new varieties has been adopted. It was considered advisable to follow this course for the purpose of protecting both members and raisers from fraud and confusion. Nine new varieties have been registered during the year. The scale of points for judging and for awarding certificates and awards of merit to new varieties has also been altered, and the new scale is reproduced for general information A variety must gain at least 85 points to entitle it to a first class certificate, and 75 points to entitle it to an award of merit. Colour, 20 points; size, 20; fragrance, 10; substance, 10; calyx, 5; habit of plant, 20; and form, 15; total, 100.

As a means of helping amateurs, an expert grower was appointed to give an address on "The Cultivation of the Perpetual Flowering Carnation" in the Lecture Room of the R.H.S. hall, on the afternoon of the April show, and the thanks of the society are due to Mr. P. Smith, of Medstead, for the very practical manner in which he fulfilled this duty. On the occasion of the December show a question box was placed in the hall, and a number of visitors availed themselves of the opportunity of writing questions and placing them therein. These questions, and a number of oral questions, were answered in the lecture hall by Mr. P. Smith and Mr. M. C. Allwood, and the thanks of the society are due to these gentlemen for the able manner in which they replied, their advice being warmly appreciated by the audience.

Your committee considered it desirable that the society should be in a position to award medals of its own, and, after much deliberation, a drawing was approved, and a die cut. It was hoped that the medals would have been on view and ready for the December show, but the designers were unable to complete the medals in time. A fund was opened to procure the die, but very few members subscribed, and of the total amount received two-thirds was subscribed by members of committee.

Your committee has great pleasure in announcing that two cups have been presented to the society, one by Lord Howard de Walden, and the other by the American Carnation Society. It has been decided that these two cups shall be held as challenge cups in perpetuity.

Your honorary secretary is in touch with Mr. Albert M. Herr, the secretary of the American Carnation Society, on the subject of the compilation of a complete list of perpetual flowering carnations, with a view to the framing of a list of too-much-alike varieties. When the necessary information, which has been promised this society by Mr. Herr is forthcoming, the work will be taken in hand by your Floral Committee.

The society has lost seven members by resignation, 27 struck off for non-payment of subscriptions, and one by death, viz., Martin R. Smith, Esq., one of the vice-presidents of the society. His loss is one that will be deeply felt, not only by the members of this society, but also by every true lover of the carnation. Fifty-one new members have joined during the year, and the total membership of the society at December 31, 1908, was 179.

The balance-sheet showed that, including £4 1s. 7d. brought forward, the income was £172 18s. 4d., and the expenditure £147 15s. 1d., leaving a balance of £25 3s. 3d.

The Chairman moved the adoption of the report and balance-sheet, and referred briefly and lucidly to their main features. He regretted the small attendance and the poor gate at the December show, and urged that if the society's usefulness was to increase a large accession of members would be necessary. Mr. Cook seconded the motion, which was carried.

A hearty vote of thanks was accorded Mr. Brunton for his services as chairman, on the motion of Messrs. Mason and Mathias. The adoption of the balance-sheet, taken as a separate item, was moved by Messrs. Curtis and Waters, and carried.

A slight alteration of rules, having the effect of pointing out that 5s. was the minimum annual subscription, was made, and then Lord Howard de Walden, who is offering a splendid new silver cup for competition this year, was re-elected president. Messrs. Baker, Raphael, Turnbull, Byass, Johnstone, and Brunton, and the Rev. J. Jacob were elected vice-presidents.

Mr. Brunton was re-elected chairman, and Mr. S. Mortimer as vice-chairman. Mr. Hayward Mathias was re-elected hon. secretary, but, in deference to his wishes, the treasurership was separated from the secretarial work, and Mr. L. J. Cook was elected treasurer.

The chairman then presented the medals won to their respective winners, and the election of committee was then proceeded with. There were six vacancies to fill, and those elected were Messrs. W. H. Page, H. F. Mason, W. A. Sherwood, W. E. Wallace. M. C. Allwood, C. F. Waters, and the Rev. J. Jacob.

Messrs. C. H. Curtis and R. Pinches were re-elected auditors. Some discussion ensued relative to the holding of one exhibition in the provinces, and the committee was instructed to consider the subject. The proceedings closed with a vote of thanks to the chairman.

Royal Gardeners' Orphan Fund.

There was a small attendance at Simpson's, 100, Strand, on February 12, when the annual meeting of the above-named excellent and extremely useful charity was held, under the presidency of Mr. H. B. May, the chairman of committee. There were sixteen persons present when the proceedings opened; evidently the subscribers have every confidence in the committee, but their absence is not very encouraging to the workers.

The usual formalities were proceeded with, including the reading of the minutes of the previous annual meeting.

REPORT OF COMMITTEE.

It is with great gratification and a deep sense of thankfulness that at the close of the twenty-first year of the existence of the fund the committee is enabled to present a report which they believe will afford the liveliest satisfaction. The receipts from all sources in 1908 amounted to no less a sum than £2,694 1s. 9d. More than half of this amount was obtained by the appeal made at, and in connection with, the Coming-of-Age Festival held in May, which will be long remembered as an interesting event in the history of the fund. The committee acknowledges with deep gratitude their indebtedness to their noble president, the Duke of Bedford, for presiding on that occasion, for his Grace's sympathetic appreciation of the beneficent work which is being carried on, his eloquent commendation of the claims of the fund to the generosity of all interested in gardeners and gardening, and for his munificent contribution of £250 to the festival dinner list. To Mr. N. N. Sherwood and his sons, Mr. William and Mr. Edward Sherwood, whose practical sympathy with the objects of the fund, from the day of its foundation, has helped materially in placing the charity in its present position, grateful thanks are accorded for their generous presentation of £391 Metropolitan Railway 3½ per cent. preference stock to endow the "Maybud Campbell Grant" of £13 per annum to an orphan girl selected to receive same under the rules of the fund. The appeal made on the initiative of Mr. H. J. Clayton, for a special coming-of-age gift to the fund, to be raised by means of a shilling collection, resulted in the receipt of the handsome sum of £250, and the committee tender their grateful thanks to all who assisted in bringing about such an appreciable addition to the fund's exchequer.

The net result of the year's work is an increase in income over that of the previous year, amounting to £747 11s. 7d. This sum has enabled the committee to increase the allowances and grants in aid made to the poor children by the sum of £109 17s. 6d.; to add £596 7s. 7d. to the reserve fund, £85 to the deposit account, and to increase the balance carried forward by £77 9s. 2d.

At the commencement of 1908 there were 106 children receiving the full benefits of the fund. Seventeen more were added to the roll at the annual meeting, held in February. At the close of December the number on the elected list was 104, while 21 of the candidates awaiting election, greatly being in need of assistance, were receiving compassionate allowances. The total sum distributed among the beneficiares during the year was £1,621 7s. 6d., the highest total yet reached. The number of children elected to receive the benefits of the fund since its foundation is 253, and the total expenditure in weekly allowances and grants in aid during the same period is £19,506.

The next festival takes place on Thursday, May 6, at the Hotel Cecil, when his Grace the Duke of Rutland has most kindly consented to preside. The committee make this announcement with extreme pleasure.

For some years past the fund has greatly benefited by the exertions made on its behalf by the committees of the Chesterfield and District Chrysanthemum Society, the Altrincham and District Gardeners' Mutual Improvement Society, the Chislehurst Gardeners' Mutual Improvement Society, the Bradford Chrysanthemum Society, and similar institutions. The committee are glad to record the fact that during the year several additional societies of this character have caused their names to be enrolled among the regular contributors. To one and all who have helped the fund in this way most cordial thanks are tendered. The committee also again most gratefully acknowledges the valuable support accorded to the fund by the owners of private gardens, who kindly open their establishments to the public from time to time in aid of this and other charities. In this connection special thanks are due to Mary, Countess of Ilchester, Sir Frank Crisp, and Major John W. Dent, for valued contributions.

The committee has again, unhappily, to deplore the loss the fund has sustained by the hand of death. As former colleagues, the valued services of Mr. George Nicholson and Mr. C. E. Osman are gratefully remembered, as also are the active services rendered in the early days of the fund by Mr. W. J. Brewer and Mr. Henry Hawkins; whilst in recent years Mr. W. Neild, Mr. R. Lye, and Mr. Joseph Lee, were all devoted adherents to the children's cause. The late Mr. J. Cawthra, of Bradford, and Mr. Benjamin Greaves, of Horsham, were annual contributors, and legacies of £150, less duty, from the former gentleman, and £50 from Mr. Greaves, are thankfully acknowledged.

The members of the committee who retire by rotation are Mr. W. Bates, Mr. G. L. Caselton, Mr. C. Dixon, Mr. H. B. May, Mr. J. W. Moorman, Mr. Whitpaine Nutting, Mr. G. Reynolds, and Mr. J. H. Witty. These members, being eligible, offer themselves for re-election.

To the auditors, Mr. M. Rowan and Mr. P. Rudolph Barr, the committee again tender their sincere thanks for the valuable services they render the fund from year to year by their exhaustive examination of the accounts. The retiring auditor is Mr. Barr, and with great pleasure the committee recommends his re-election.

In concluding this report the committee again appeal with confidence to the liberality of all those who recognise the legitimate claims of necessitous orphans. In the ranks of gardeners, as in those of most other callings, there are many distressing cases of premature death. The breadwinner is suddenly removed from the scene of his labours, whilst still young, and, therefore, before he has had time and opportunity to provide for those dependent upon his industry. The widow, being often left with several children of tender years, she is unable to use her capacity for earning a living, because her presence and care are needed at home. Surely, the cry of the children is one that we have no right or desire to disregard!

The amount of good that follows the disbursement of small sums to children, is out of all proportion to the sums contributed, and not only is this the case, but in helping the children by ensuring to them the necessities of life, the heavy lot that oppresses the young widow is materially lightened.

The committee, therefore, believe that, in the future, as in the past, the Royal Gardeners' Orphan Fund will receive such a measure of support as will enable it to continue the work it has faithfully discharged in the past twenty-one years.

In proposing the adoption of the report and balance-sheet the Chairman pointed out that the receipts for the year were distinctly in advance of previous years, this being due chiefly to the beneficences of the Duke of Bedford, Mr. N. N. Sherwood, Mr. E. and Mr. W. Sherwood, and the result of the Clayton Shilling Fund. He briefly reviewed the chief points raised by the report, especially thanking those who had opened their gardens for the benefit of the charity, and assisted it in other ways. He also referred feelingly to the loss sustained by the death of Messrs. G. Nicholson and Osman, and expressed his regret that so few subscribers had come to the meeting. Mr. William Marshall formally seconded the chairman's proposal, and the motion was carried.

Mr. R. H. Pearson proposed hearty thanks to the president, the Duke of Bedford, for presiding on the occasion of the twenty-first festival dinner last year, and he pointed out that the great success of the festival was due largely to his Grace's presence and generosity. Mr. W. Cutbush seconded the motion, and it was carried. Mr. W. Roupell proposed, and Mr. George Gordon seconded, the re-election of Mr. E. Sherwood as treasurer, and this was unanimously agreed to. Mr. P. R. Barr was thanked and re-elected as auditor, on the motion of Messrs. W. Poupart and Alderson.

The re-election of Messrs. Bates, Caselton, Dickson, May, Moorman, Nutting, Reynolds, and Witty as members of committee was proposed by Mr. Alex. Dean, in a very able speech. He pointed out that Messrs. Bates, Roupell, and Wynne were the only persons present who belonged to the original committee. He pointed out that vast sums of money were often spent by charities on buildings and on a big staff of officials, the cost of management often amounting to 8d. in every shilling received by the charity. In the Orphan Fund they had avoided that great mistake, consequently by far the greater part of the monies received went directly to maintain the orphan children. He congratulated the subscribers on having such a hard-working and cheerful committee, and the committee on having the management of such an excellent institution. Mr. Alderson seconded the motion, which was carried.

The Chairman proposed the re-election of Mr. Bryan Wynne as secretary, at a salary of £200 per annum. In doing so he pointed out that offices had been taken in Milton House, Surrey Street, at a cost of £25 a year, and Mr. Wynne would now devote the whole of his time to the interests of the fund, and further clerical assistance would not now be necessary. Mr. W. Bates seconded the motion, which was carried unanimously.

On the motion of Mr. Campbell Messrs. Bates, Ingamells, Lyne, Moorman, and Poupart were appointed scrutineers of the ballot, and the meeting was then adjourned until the declaration of the poll.

There was a modest increase in the attendance when the result of the election was announced. The votes recorded, and the names of the twenty successful candidates were given,and then Mr. Harry J. Veitch appealed to the committee to place the five unsuccessful candidates on the funds, and, receiving a favourable reply from the chairman, he moved that this be done. Mr. George Gordon seconded the proposal, Mr. A. Dean supported it, and the committee concurred, and so there was an unanimous and favourable vote.

Votes of thanks to the scrutineers and chairman concluded the proceedings.

Reading Gardeners' Association.

One of the most interesting lectures delivered in connection with the above association was that given in the Abbey Hall, on Monday evening, by Mr. W. Shipway, one of Messrs. Sutton and Sons' experts on grasses, the subject being "Lawns and Lawn Grasses." Mr. Alderman F. B. Parfitt, president of the society, occupied the chair.

To the ordinary individual a lecture on this subject would probably appear a somewhat dry and uninteresting matter, but to those who have the management and upkeep of a lawn, or series of lawns, it proved a highly instructive and enjoyable evening.

Seventy lantern slides were used by the lecturer to illustrate his remarks, many of these being beautiful pictures of lawns, tennis grounds, bowling greens, etc., produced in different parts of the country; others depicted the method of preparing the soil, draining, levelling, seed sowing, etc. Two of the slides, one showing a plot of grass infested with nearly all the weeds to which a lawn can be heir, the other a picture of the same plot after treatment by Sutton's lawn sand, created astonishment among the audience.

From the following syllabus it will be readily understood that the paper was indeed most exhaustive and comprehensive. Syllabus: Situation and aspect, drainage, soil, imported soil, digging and enriching soil, levelling ground, cleaning the ground, surface preparation, turfing and seeding, differences of lawns, lawn grass seeds, mixing seeds, quantity of seed required, sowing seeds, lawn grasses, clover in lawns, treatment of a new lawn, mowing and rolling, manures (natural and artificial), thin turf, weedy turf, mossy turf, earthworms, and implements.

When, having spoken for nearly an hour and a-half, Mr. Shipway resumed his seat, he was much applauded. In the discussion which followed the lecturer was able to largely amplify his remarks in answering the many questions put to him, and inquiries relating to such important matters as suitable grasses for sowing on a lawn shaded by trees, the eradication of moss, application of natural and artificial manures, the best artificials, and the destruction of earthworms by the application of worm destroyer, were fully answered by Mr. Shipway. The debate was sustained by the President, Messrs. Hinton, Exler, Sale, Wicks, Herridge, T[illegible]bridge, Carter, Loader, and others.

Mr. F. Townsend, head gardener to the vice-president, exhibited a fine group of primulas, embracing The Duchess, The Czar, Reading Blue, White Queen Star, and Lord Roberts Star. Four new members were elected. A vote of thanks to the lecturer, which was carried with acclamation, concluded the meeting.

Birmingham Gardeners' Association.

At the recent fortnightly meeting Mr. A. Coombes, St. Mary's Nursery, Hagley, near Stourbridge, gave an address on "Peach and Nectarine Culture." Mr. Thomas Humphreys (the chairman) presided over an appreciative assembly of the members. Mr. Coombes, who has been a most successful cultivator of fruits, especially of those forming the subject of his address, gave a ver[illegible] discourse both as to the outdoor and under-glass treatment in a very lucid and practical manner. Commencing with the selection of the maiden trees, composition of the soil, and the mechanical construction of the borders, he also adverted to that phenomenon "bud dropping," which, so far, is an unsolved problem, a fertile source, however, being imperfectly ripened wood, extreme dryness at the roots during the "resting season," and followed by an excessive application of water at the commencement of the forcing season. Another remarkable fact is that certain varieties of peaches and nectarines are naturally prone to drop their buds, which is accelerated by the mode of treatment when grown under glass. Mr. Coombes also expressed his regret at the decline of the cultivation of the peach and nectarine in the open, a circumstance arising not from any appreciable change in the climatal conditions from the normal conditions of half a century ago, but probably due to the attention of the cultivator being drawn away by the numerous exigences of [illegible] in the wonderful degree of popularity accorded to floral decorations. At the conclusion of the address only a short time was available for the animated discussion, and Mr. Coombes was accorded a hearty vote of thanks.

United Horticultural Benefit and Provident Society.

The monthly committee meeting of this Society was held at the Royal Horticultural Hall, Vincent Square, Westminster, on Monday evening, February 8, Mr. Charles Curtis in the chair. Eleven new members were elected. Two members were allowed to transfer from the lower to the higher scale.

The annual meeting will be held at the Royal Horticultural Hall on Monday, March 8 next, at 8 p.m., when Mr. Charles H. Curtis, chairman of committee, will preside.

Royal Horticultural Society.

SCIENTIFIC COMMITTEE, February 9. Present: Mr. E. A. Bowles, M.A., F.L.S., F.E.S. (in the chair); Messrs. C. T. Druery, H. T. Güssow, G. S. Saunders, A. Worsley, J. T. Bennett-Poë, W. Hales, F. J. Chittenden (hon. secretary), and Gurney Wilson (visitor).

BEETLE IN STEM OF VANDA. — Mr. Saunders reported that the beetle in the stem of Vanda teres was in too immature a condition to determine.

MALFORMED ORCHID.—Mr. Saunders also reported that the flower of Cattleya Trianæ referred to him from the last meeting showed three perfect stamens surrounding the pistil, three very short and regular petals, and three sepals shorter still. Mr. Saunders showed drawings illustrating these points.

ALBINISM IN ORCHIDS. — Mr. Gurney Wilson exhibited specimens in illustration of the inheritance of albinism in dendrobiums. He found that Dendrobium Murrinianum crossed with D. Ballianum, the former not a pure albino, though pale, the latter nearly white, gave seedlings almost exactly like typical D. nobile. D. nobile alba (virginale) which, when selfed, gives quite white seedlings, when crossed with D. Findleyanum gives D. "Cybele," all the seedlings being alike, and no light forms among them. Similarly Dendrobium Wardianum album crossed with D. nobile alba gives all coloured flowers. These "reversions" to coloured forms confirm the results that have been obtained in crossing sweet peas and stocks.

DOUBLE CYCLAMEN.—Mr. L. Lawrence, gardener to R. Gregory, Esq., of Shoreham, exhibited a plant of cyclamen bearing double flowers. The seed was from Low's Cyclamen Salmon Queen, and this was the only plant which had produced such flowers. All the flowers on the plant were alike, and every one had five perfect flowers arising from within the calyx, probably axillary to the sepals, though apparently alternating with them, and surrounding the central corolla, etc.

HIPPEASTRUM PARDINUM. — Mr. A. Worsley exhibited flowers of a form which he regarded as belonging to this species. He considered the species to be a variable one, and the form figured in the "Bot. Mag.," 5, tab. 5,645, not to be the one most commonly met with.

NOTONIA GRANTI. — This interesting composite with bright red heads of flowers and Kalanchoe-like in habit, about 3ft. in height, a native of Uganda, was exhibited by Messrs. J. Veitch and Sons. It was recommended that a botanical certificate be awarded to it. It was figured in the "Botanical Magazine," tab. 7,691.

British Gardeners' Association.

The monthly meeting of the London Branch of the association was held on February 11 at Carr's Restaurant, Strand, when Mr. E. F. Hawes presided. There was an excellent attendance, those present including: Mr. F. G. Cole, superintendent at the Garden City, Letchworth; Mr. Cresswell, gardener to the Earl Lytton; and Mr. C. B. Usher, newly home from Central Africa.

A brisk discussion upon the "Elm Bark Beetle" followed the formal business, but no satisfactory remedy for the pest seemed to be forthcoming.

After the discussion of this, and a few other points, a very interesting lecture upon "Kew Gardens: Their History and Attractions" was given by Mr. Charles H. Curtis, of the Gardeners' Magazine staff. Mr. Curtis briefly reviewed the history of the gardens at Kew from the time of Wm. Turner down to the present, and he showed how since they became public property the gardens had increased in size, beauty, and usefulness. He pointed out that, in addition to their great beauty and value from a purely gardening point of view, the gardens exerted a wonderful influence in two other directions. They were the centre of botanical science, and included a magnificent herbarium and botanical library; and they were of the utmost importance to the Empire in its work of colonisation, and the improvement of the agri-horticultural conditions in the dependencies.

Dealing with the attractions of the gardens, Mr. Curtis described the leading features of this great national institution, and, by means of nearly eighty fine lantern slides, vividly illustrated his remarks. The views of the Palm House, Rock Garden, interiors of the North Gallery, Timber Museum, Pagoda, Temperate House, Lake, and Rhododendron Dell, drew forth rounds of applause. Following the lecture, Mr. Curtis, in answer to questions, outlined the advantages to be derived by young gardeners from a couple of years' employment at Kew.

A cordial vote of thanks to Mr. Curtis, and a similar vote to the chairman, who also kindly acted as lanternist, brought an interesting, pleasant, and instructive meeting to a close.

Bristol Gardeners' Association.

"Hardy Ferns" was the topic at the meeting held on Thursday, February 11, at St. John's Parish Rooms. Dr. Shingleton Smith presided over a large attendance. Mr. Tunbridge, representative of the Reading Association, delivered a most interesting lecture upon the subject noted, full of poetry and humour, as well as cultural details and historical facts. The lecturer said some of the British ferns were used for food and medicinal purposes, and they were a survival of ancient times. Many of these ferns are beautiful. Speaking of the mystery of germination, Mr. Tunbridge said there were three stages, spore, prothallus, and the plant. Considerable care is required in raising ferns from spores, it being essential in all stages that they should have warmth, moisture, and shade.

Mr. Tunbridge had on view a splendid collection of fronds, consisting of over one hundred varieties, with names attached, which proved to be highly educational to the members. The lecturer said each name was of some significance, and described some special feature.

The chairman opened the discussion, adding some items of interest, and mentioned that the extract of male fern was used as a remedy for the tape worm, and also that we are indebted to the monster tree ferns of ages ago for our present supply of coal. Messrs. Candy, House, Holt, Binfield, Woodward, Scott, and Thoday also took part in the discussion, after which hearty votes of thanks were passed to lecturer and chairman.

For two table plants Mr. Grieve was first and Mr. Curtis second. A special certificate went to Mr. Tunbridge for his collection of ferns, and an ordinary one to Mr. Woodward for Cycnoches chlorochilum (Swan Orchid).

The East Anglian Horticultural Club.

The February meeting of this club witnessed a bright and interesting exhibition of flowers, fruits, and vegetables, contributed by its members. The educational side was well maintained by a lecture given by Mr. C. H. Shipston, of Ipswich, upon chemical manures. There was not much in the way of phosphatic, potash, or nitrogenous fertilisers that Mr. Shipston did not know about, and remark upon their fertilising properties. His proportions to use of the several well-known chemicals for various crops was carefully noted. A good discussion followed, and Mr. Shipston received the warm thanks of a large assembly for his lecture.

DESTRUCTION OF VERMIN. — Most gardens are pestered with Rats and Mice. Every effort should be made at this time of the year to exterminate them before seeds are sown. Danysz Virus is first rate stuff for killing these vermin. Single tube, 2s.; three tubes, 5s. Post free from DANYSZ VIRUS LTD., 52, Leadenhall Street, Garden Dept., London, E.C.—[Advt.]

RED OR GRIZZLY GRAPES.

Mr. Molyneux seems to argue (page 124) as if the fact that Grizzly Frontignan grape is very little grown were absolute proof that it is not worth growing. Such logic will scarcely hold water, as a similar statement might have been made only a few years ago about Cox's Orange Pippin apple, the time being well within my recollection when we burned hundreds of fine trees because the public would not have them at any price, preferring King of the Pippins.

Disputes on matters of taste are proverbially futile, but my own opinion is that Grizzly Frontignan is the most delicious grape in cultivation, even surpassing the Muscats in flavour, and without the "cloying" quality which some palates object to in the Muscats.

Pot vines being a speciality of our nurseries, I have had pretty full opportunities of hearing buyers' opinions on grapes, and may say that the neglect of "grizzly" sorts is owing to two causes. Firstly, the employer usually prefers fruit that will make a show on the table, and not one in fifty would have the moral courage to put a bunch of Frontignans before a guest, for fear that he should be suspected of palming off inferior fruit upon him.

Secondly, red grapes, to most gardeners, are as a flag of the same colour to a bull, and the warmth of Mr. Molyneux's denunciation would seem to indicate that he shares the feeling. Red or grizzly grapes are generally looked upon as a glaring proclamation of incompetence on the part of the grower, and it is consequently not to be wondered at that most gardeners absolutely refuse to have anything to do with growing fruit which might create a wrong impression in the minds of the ignorant visitor.

Perhaps when the Wisley exhibits, and the efforts of those who prefer flavour to show, have made the public more familiar with grizzly grapes, the Grizzly Frontignan will "come into its own," and, I may add one other little point, viz., that it will finish in an orchard house or other unheated structure, thus making it an amateur's fruit, which the much-lauded Muscat of Alexandria is not. Chas. E. Pearson.

Lowdham Nurseries.

"Chrysanthemums for Garden and Greenhouse."—This book, written by Mr. D. B. Crane, has now passed into a second edition. The work has undergone thorough revision, and has been much improved and brought up-to-date. All the new varieties are described, and in many cases illustrated; also new illustrations have been added of the chief insect friends and foes. Culture for cut flower production and garden decoration is the theme of this treatise; it includes the early-flowering section, decorative Japanese, pompons, singles, etc. The book is nicely bound in cloth, and is offered for 2s. 6d. net, or by post 2s. 10d., from W. H. and L. Collingridge, 148, Aldersgate Street, London.

Oxalis floribunda.—This common oxalis, with its bright display of rose-coloured flowers, most of the summer, is a useful plant for certain purposes. Though it will grow in almost any soil, it does best on one inclining to lightness. Its flowers open in the sun, and close towards evening, so that a sunny situation is necessary to show it off to advantage. It is very showy on the margin of a mixed border, though it should not be planted too close to the edge, as its leaves and flowering stems come forward as the plant develops during the summer. It is also good between taller plants, when it is not too much sheltered from the sun by them. On the rockery, too, it is valuable, a good patch of it growing downwards at an angle of 45 degrees in full sunshine being very effective. It has a tuberous root, and is easy to propagate by division, though on some favourable soils it needs repression rather than propagation.—Alger Petts.

NEW PLANTS, ETC.

◆

ODONTOGLOSSUM ARDENTISSIMUM PHŒBE.

This beautiful variety has very fine form and particularly rich colouring to recommend it. Reference to our illustration on page 134 will show that the rich red-purple colouring occupies the larger part of each sepal and petal, this vivid colouring being set off by the white margin. The lip is large, and has a white apex, and a bright red-purple area, extending over the base and down the centre. F.C.C., R.H.S., February 9. Mr. Norman C. Cookson (gardener, Mr. H. J. Chapman), Oakwood, Wylam-on-Tyne.

CYPRIPEDIUM LEANDER, EXHIMS VAR.

This shapely hybrid is derived from C. villosum and C. Leeanum var. The rounded dorsal sepal is white, with rosy-purple markings, while the broad petals are light yellowish-green, with shadings of dull purple, and the lip is similarly coloured. A.M., R.H.S., February 9. Mr. J. Forster Alcock, Exhims, Northchurch.

LÆLIO-CATTLEYA GOLDFINCH SUPERBA.

A charming hybrid, obtained from L.-c. Warnhamensis and C. Dowiana aurea. This cross has given progeny showing considerable variation, but the above variety is very striking, because of the deep rich purple colouring of the lip, this being finely displayed by the bright yellow of the sepals and petals and the golden lines at the base of the lip. A.M., R.H.S., February 9. Lieut.-Colonel G. Holford (grower, Mr. H. G. Alexander), Westonbirt, Tetbury, Gloucester.

ALPINIA BRACTEATA.

A strong growing, moisture loving plant from the Eastern Himalaya, and one that thrives under cultivation in a tropical house, planted in rich soil. It grows from 3ft. to 7ft. high, produces bold leaves, often 2ft. long and 6in. broad, and bears fairly large bright flowers on a terminal raceme. The flowers are white, tinged with pink, and have a large lip that is red-purple, with rosy margins and a yellow tip. Bot. Mag., t. 8,237.

OLIGOBOTRYA HENRYI.

A very curious Chinese liliaceous plant growing about 3ft. high, with slender purple-marked stems and rounded green leaves. The flowers may be yellow or violet, but they are small, and produced in a terminal spike. The plant is hardy, and succeeds with hardy cypripediums. Bot. Mag., t. 8,238.

ERANTHEMUM WATTI.

This is a handsome and useful garden plant, and one that was introduced by Colonel R. H. Beddome, from Northern India. It was first figured in the GARDENERS' MAGAZINE of 1901, p. 645, and there described under the name of Dædalacanthus Watti, the title given it at first by Colonel Beddome. The species was discovered by Sir George Watt, whose name it bears. E. Watti is easily grown in a warm house from spring-struck cuttings, and it will then flower freely in July and August, yielding an abundance of violet-blue flowers on neat, much-branched plants. Bot. Mag., t. 8,239.

PINUS BUNGEANA.

A tall-growing pine from Northern China, and one that succeeds well at Kew, where there is a specimen 25ft. high. It is an attractive tree, with vivid green leaves, and smooth bark, that peels off after the manner of the common plane. The leaves are in bundles of three, and the cones are from one to two inches long. Bot. Mag., t. 8,240.

SORBUS VILMORINI.

A very distinct new species found in South-western China. Specimens were sent to Kew in 1887, but it was not until 1905 that a living plant was received, through the kindness of Mr. M. L. de Vilmorin, in whose fine collection of trees and shrubs at Les Barres, the species has grown to a height of 10ft. The plant is hardy, flowers freely in June, bearing terminal corymbs of white flowers, which are followed by red, rounded fruits that are attractive in September and October. Bot. Mag., t. 8,241.

OBITUARY.

◆

MR. W. Y. GIBSON.

In his eightieth year, Mr. W. Y. Gibson, a well-known Aberdeen resident, died a few days ago, after a long life spent in the seed and nursery trade. He was best known for his long connection with the firm of Messrs. Benjamin Reid and Co., of Aberdeen, and was intimately associated with the seed and florists' departments of that firm. He retired from business only a short time ago.

SIR GEORGE KING.

We regret to record the death of Sir George King, K.C.I.E., which occurred on the 13th inst. at the Hotel des Anglais, San Remo, in his sixty-ninth year. Sir George King entered the Bengal Medical service in 1865, and was for some years house surgeon of the hospital attached to the Medical College in Calcutta. Here his interest in botany was recognised, and in 1871 he was appointed to the botanical chair of the college, and also to the post of director of the Calcutta Botanic Gardens, where he accomplished much useful work. Sir George King devoted much attention to the investigation of the alkaloids of cinchona bark, and was appointed superintendent of the cinchona plantations in British Sikkim. In 1891 he was appointed an additional director of the Botanical Survey of India, retaining his charge of the gardens. Chief among the several works from the pen of Sir George King may be mentioned, "Manual of Cinchona Cultivation in India." "Orchids of the Sikkim Himalayas," and "Species of Ficus of India and China."

TRADE NOTES.

Chief among the difficulties with which cultivators of peaches and nectarines against open walls have to contend is the prevention of the disease commonly known as leaf-curl and peach blister, which, in districts not particularly favourable to the growth of these fruits, annually does much damage to the trees, unless preventive measures are adopted. By past generations of growers the blistering and curling of the leaves was regarded as the result of the disorganisation of the cells by the cold easterly winds, usually prevalent at the time when the tender foliage is unfolding; but scientific research has established the fact that the disease is caused by a fungus known as Exoascus deformans, which is most rife in seasons when the growth is checked at an early stage by a sharp fall in the temperature. Good culture is of much value in warding off attacks, but it is not all-sufficient, and it is therefore a point of much importance that cultivators should have at their command a cheap, effectual, and easily-applied remedy, such as that which Messrs. George Bunyard and Co., of the Royal Nurseries, Maidstone, have introduced under the name of Medela. This is a liquid preparation, and, in being prepared for use, is mixed with soft water at the rate of half a pint of the specific to half a gallon of water. It is then applied with a hand sprayer, or a syringe, to which a fine rose has been affixed, care being taken to thoroughly saturate the whole of the shoots. It is advised that the first spraying be at the middle of February, or as soon after as practicable, and that the trees be again sprayed early in March. Should there be evidence of the presence of the disease later on, the trees should be sprayed with a solution of one-half the strength of that advised for the earlier sprayings.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

BAIT FOR MOLES.—C. F. A., Kidderminster: We have never seen a mole trap baited, and cannot, therefore, offer you any advice as to the kind of bait that would attract moles to the trap. If any of our readers know of a good bait for moles we shall be glad if they will tell us what it is.

RED LEAD FOR SWEET PEAS.—C. F. A., Kidderminster: Dry red lead does not in any way injure the seeds of either culinary or sweet peas if applied properly. The method is simplicity itself, and consists of placing the seeds in a tin or iron or earthenware vessel, preferably a moderately shallow one. Pour a little water upon the seeds, and then, with a circular motion, ensure that every seed is wetted. Drain off all the surplus water, and then dust the seeds with dry red lead. Repeat the circular motion until every seed has its thin coating of red lead, then set the seeds aside to dry, and, as soon as they are dry, sow them. Put on an old pair of gloves when doing the work, and take care not to inhale the red lead, as it is very poisonous. However, with reasonable precautions there is no danger to the operators, but the leaded seeds are fatal to birds and vermin, and they come quickly to know this, and give the seed a wide berth.

BEGONIA WORTHIANA.—F. M., Ewell: Your best method will be to start the tubers in shallow boxes of rich, light soil in a warm, moist house, and, as soon as they are available, make cuttings of the young growths, inserting each one in a small pot, in sandy soil, and placing them in a propagating frame.

COUCH GRASS IN ORCHARD.—F. E. C., Norwich: We entirely agree with you that it will be far better, and much more profitable, to cultivate the ground between the orchard trees. If the couch and other grasses are as bad as your letter suggests you will have to deal with the matter in bold fashion. We suggest you start several good fires going down the centre of the orchard, making them up with wood obtained from the prunings, etc. When the fires are of some size dig up the surface soil containing the grass roots, or pare it off if the roots are not too deep, and burn it on the fires. As the paring process proceeds have the ground deeply dug and left rough. When all the rest of the orchard has been thus cleaned and dug, work down the centre, and distribute the ashes from the fires over the whole area. This is good work for the first thing in the morning and the last thing in the afternoon. Plant potatoes in due course, as the hoeing and earthing up these need give the ground a thorough cleaning.

RAISING SWEET PEAS IN POTS.—D. H., Derby: You will find the whole subject fully and practically dealt with in "Sweet Peas and Their Cultivation," a capital little book, freely illustrated, and containing full information as to varieties, raising, planting, staking, feeding, etc. The book is by Mr. C. H. Curtis, hon. secretary of the National Sweet Pea Society, and can be obtained from the GARDENERS' MAGAZINE Office, 148, 149, Aldersgate Street, E.C., for 1s. 2d. or 1s. 8d. (cloth boards), post free.

BOUVARDIA CULTURE.—G. B., Cirencester: Bouvardia blooms are very useful for buttonhole bouquets, while for supplying quantities of useful and lasting flowers, and for the decoration of the conservatory and greenhouse, bouvardias have much to recommend them. A succession of young plants is essential to the plentiful production of bloom, and they may be readily propagated from the cuttings of young shoots in the spring. To obtain suitable cuttings rest the old plants for a short time after they have flowered, then cut them hard back, and place where they will have the assistance of a brisk temperature. The result will be a crop of new growths that can have their tops taken off and rooted with the greatest ease. Use fibrous loam and peat, three parts each, and leaf-mould and sand one part each. Grow in a pit or frame during the summer, and in the winter in an intermediate house. The finest of the varieties are Alfred Neuner, Candidissima. Dazzler, Humboldti corymbiflora, Mrs. Green, Priory Beauty, Purity, Thomas Meehan, Triomphe de Nancy, President Garfield, and Vulcan.

SOWING TOMATOES.—M. P., Prescot: Some growers sow tomato seeds fairly thickly in pots or pans, and pot off the seedlings as early as possible, and when circumstances are such that potting can be done the moment it is necessary good results follow. Failing these conditions there is great risk in thick seed sowing, because the seedlings may become drawn, weak, and starved before they can be transferred to single pots, and they then take some time to recover, and there is a consequent loss of crop. We prefer to sow the seeds in broad boxes about four inches deep, placing the seeds an inch apart every way, just comfortably covering them with fine soil, and pressing this down firmly. It takes longer to sow in this fashion, but the plants come along sturdily, and there is not the necessity for potting them off so quickly as when the seedlings stand close together, and are competing with each other for the necessities of life.

ASPARAGUS FOR SMALL GARDENS.—C. T. E., Hendon: Asparagus is by no means difficult to cultivate, but it is not usually considered a suitable vegetable for small gardens, because the space necessary for beds sufficiently large to provide a good dish at any one cutting is considerable. However, you must decide for yourself. In forming a new plantation select ground that was trenched in the autumn, and had plenty of manure and some lime rubble added. Grow in beds five feet wide, with two-feet alleys between them, and put three rows in each. The best time for planting is at the end of March or early in April, when the crowns are commencing to make new growth, and the best way of doing this is to make drills six inches wide, place the roots in them twelve inches apart, and cover with fine soil. A dressing of half-rotted manure in the autumn is desirable each year, as also is a dressing of nitrate of soda in the spring, at the rate of half an ounce to the square yard. If manure is not available, top-dress in the autumn with bone superphosphate and kainit at the rate of two ounces each to the square yard. Connover's Colossal, Early Giant French, and Giant Argenteuil are good types.

SCENTED BEGONIAS.—M. E. M., Newport: There are very few begonias with fragrant flowers, and those that have a distinct odour seem to lose it under the influence of hot sunshine or dry atmosphere. It is in early morning that the fragrance is most noticeable. Begonia Baumanni, introduced from Bolivia about 1866, by Dr. Sace, and first raised from seed by Mr. E. N. Bauman, of Bolwiller, was purchased by Mons. Lemoine, of Nancy, and distributed by him in 1892. This produces flowers that are more or less fragrant. This has been used for crossing with the double tuberous varieties, and has resulted in the few varieties that possess a little fragrance. But we appear to be a long way yet from garden varieties of tuberous begonias that are decidedly and continuously fragrant.

NAMES OF PLANTS.

T. R. E., Overton.—1, Galanthus Elwesi; 2, Eranthemum pulchellum.

M. C. A., Darlington.—1, Cochlioda vulcanica; 2, Odontoglossum Harryanum.

F. G. L., Leyton.—1, Begonia fuchsioides; 2, Saintpaulia ionantha; 3, Acacia dealbata.

W. M., Lynn.—1, Woodwardia radicans; 2, Adiantum Birkenheadi; 3, Gymnogramma Alstoni; 4, Pteris cretica; 5, P. scaberula.

C. H. B., Launceston. — 1, Rhododendron arboreum var.; 2, Eucalyptus globulus; 3, Lonicera Standishi.

FORTHCOMING ENGAGEMENTS.

TUESDAY, February 23.—Royal Horticultural Society: Fruit, Floral, and Orchid Committees meet at 12 o'clock; Lecture at 3 o'clock on "A Camping Tour through Syria to Petra in Arabia," by Mr. A. W. Sutton, V.M.H.; Scientific Committee at 4 o'clock.

TUESDAY, March 2.—National Amateur Gardeners' Association: Lecture on "Garden Dahlias," by Mr. George Gordon, V.M.H., 7.30 p.m.

THURSDAY, March 4.—Linnean Society Meeting.

SATURDAY, March 6.—French Horticultural Society of London.

MONDAY, March 8.—Annual Meeting of the United Horticultural Benefit and Provident Society, at the Royal Horticultural Hall, Westminster.

Vegetables of Foreign Growth were, on the whole, less plentiful in British markets in January than they have been in the corresponding month for several years past. The most important decrease was in the imports of potatoes, of which the aggregate was only 33,365 cwt., of the value of £7,259, as compared with 572,184 cwt., of the value of £68,052 in January, 1908. In the imports of tomatoes there was a decrease in quantity of 6,387 cwt., and in value of £10,996, the total having been 67,022 cwt., of the value of £49,777. Unenumerated vegetables show an increase in value of £11,695, the aggregate having been £34,111, and in the imports of onions there was a big increase, the aggregate having been 618,980 bushels, of the value of £116,770, against 603,782 bushels, of the value of £67,499, in the corresponding month of last year.

No Garden can be Productive if Pests of the Soil Prey upon the Plants.

The growth of the garden is checked and retarded, and its life weakened, by the myriad insect pests of the soil that fatten upon plants and flowers.

Prompt treatment of the soil with the only absolutely effective pest-killer yet produced—

Kilogrub

Is the only way to remedy this evil.

Work "KILOGRUB" well into the soil, using only 2 or 3 ounces to a square yard—and let it do the rest.

It throws off poisonous fumes which are fatal to insect life, but cannot harm plants or animals.

"KILOGRUB" has been thoroughly tested, and hundreds of gardeners are glad they've tried it.

Prices, cash with order, carriage paid:—

7 lbs....	2s. 0d.
¼ cwt.	5s. 0d.
½ cwt.	7s. 0d.
1 cwt.	11s. 6d.
Sample Tin	9d.

Booklet about it free on application to

Messrs. JOHN PEAK and CO.,
Dept. K., 52, Soho Street, Wigan, Lancs.

THE FAVOURITE WEED KILLER.

SANDWITH'S
PREMIER
WEED
KILLER

As supplied to His Majesty's Board of Works, Royal Parks, etc., etc.

Use once a year, and your garden paths will be always clean and bright.

4 galls. for 7/-; drum, 2/-. 12 galls. for 19/-; drum, 6/-, 20 galls. for 28/-; drum, 10/-. 40 galls. for 52/-; drum, 20/-

EITHER LIQUID OR POWDER.

Carriage Paid.

If cash is sent cost of drum must be included which amount will be refunded when drum is returned.

TIMOTHY & SANDWITH,

The Horticultural Specialists, BRACKNELL, BERKS.

Send for our Illustrated Catalogue of Horticultural Specialities, it will interest you. Post free.

NATIVE GUANO

BEST and CHEAPEST MANURE for VEGETABLES, FRUITS and FLOWERS.

Price £3 10s. per ton in bags. Lots under 10 cwt. 4s. per cwt. at works; or 5s. per cwt., carriage paid to any station in England.

Extracts from 32nd annual collection of reports:—

NATIVE GUANO for POTATOES, VEGETABLES, etc.

J. Haydon, Hampton: "Potatoes, excellent crop; none diseased. Grand for keeping away slugs." G. Ferry, Westcliffe: "Peas and onions splendid."

NATIVE GUANO for FRUIT, ROSES, TOMATOES, etc.

A. W. Brinkham, Hull: "Cucumbers, tomatoes, and chrysanthemums highly satisfactory." G. Accleton, Carlisle: "Finest manure ever used for vines, peaches, roses, carnations, etc." W. Cooper, Shoeburyness: "Most excellent for roses."

Orders to the NATIVE GUANO CO. (LIMITED), 29, New Bridge Street, London, E.C., where 32nd year's testimonials, etc., may be obtained. Agents Wanted.

CAUSTIC ALKALI.

☞ THE FAMOUS WINTER WASH.

REMOVES all decayed Bark, Lichens, Moss & Slime.
DESTROYS the Eggs of Winter Moth & all Insects.

SPLENDID NOVELTIES.

WEBBS' NEW GUARDIAN POTATO.
3s. 6d. per peck; 12s. per bushel.

From Mr. E. Beckett, Head Gardener to Hon. Vicary Gibbs, Aldenham House, January 11/09.—"You will be glad to hear that your new Guardian Potato proved to be the heaviest cropper by far, and the best disease resister we grew during the past year, 1908; the only variety which exceeded, weight per acre, the Scotch and Irish grown seed. It is unquestionably one of the very finest main crop potatoes yet raised. I have deferred writing as to its merits till now, as I was anxious to test its keeping qualities, which are all that can be desired. I intend to plant it very largely during the coming season."

WEBBS' NEW MASTERPIECE MELON.
2s. 6d. per packet.

SUTTON AND SONS, THE KING'S SEEDSMEN, READING.

NOW IS THE TIME TO PLANT
(the best time of the whole year)
KELWAY'S BEAUTIFUL BLUE DELPHINIUMS.
Hardy, and flourishing in every garden, they are the STATELIEST of PERENNIAL PLANTS for borders or beds; these celebrated improvements are invaluable for their introduction of that precious colour—blue—in masses to the garden. KELWAY and SON developed this race, and they should be procured direct from the Royal Horticulturists, Langport.

KELWAY'S IMPROVED DELPHINIUMS are now ready, strong plants, in choice named selections. Collection "B," 15s. per doz. Collection "D," 42s. per doz. Delivery free for remittance with order. KELWAY and SON, The Royal Horticulturists, Langport, Somerset.

FRANCO-BRITISH EXHIBITION, 1908. ONE of the ONLY THREE Gold Medals (or Higher Awards) (open to the whole world for permanent exhibits) awarded by the International Jury, and confirmed by the Governing Council was awarded to Kelway and Son; vide the AUTHORISED LIST published in the Press.—KELWAY and SON, Langport, Somerset.

FOR PRESENT PLANTING.

PLANTERS of FRUIT TREES should write for our fully descriptive catalogue and supplement, 6d., post free; and gratis to customers.

Well-ripened trees of all kinds, and our large, developed specimens of Vines, Figs, Peaches, and Nectarines, are especially good.

An inspection solicited.

GARDEN PAVING, in York stone, self-faced, random, squared, etc.; also various kinds of Rock Stone. Quotations given delivered to any railway station. PULHAM and SON, 71, Newman Street, Oxford Street, London, W.

TO-DAY! AND FOR YEARS AND YEARS PAST the XL ALL Specialities are and have been the best on the market. Where is the Gardener who does not pin his faith to one or the other of these celebrated Insecticides or Fertilisers? XL ALL FERTILISER has pleased all who have used it this season. The Sales of XL ALL FUMIGATOR prove that it is more popular than ever. XL ALL LIQUID NICOTINE INSECTICIDE is always spoken of by gardeners and growers as the most deadly to Mealy Bug, Thrip, etc. XL ALL WINTER WASH for dormant Trees acts like magic, clearing the Trees and Bushes of all Insects' Eggs, Moss, and Fungoid Growths. XL ALL LAWN SAND, a weed eradicator and fertiliser for weedy and poor lawns. XL ALL WEED KILER used once a year "No weeds can live." Please ask your Nurseryman, Seedsman, or Florist for a copy of my small pink list, giving particulars of these and many other XL ALL Preparations, which can be obtained from the Horticultural Trade throughout the World. G. H. RICHARDS, Manufacturer and Patentee, 234, Borough High Street, London, S.E.

GOLD MEDAL SWEET PEAS.

ALL ENGLISH GROWN.

Awarded the Gold Medal of the National Sweet Pea Society five years in succession.

BAKER'S INTRODUCTIONS FOR 1909.

Baker's Scarlet.—A decided improvement on any scarlet in cultivation. It is of much the same colour as "Queen Alexandra," being rather brighter, but of much more vigorous growth, and, what is of still more importance, it does not scald to anything like the same extent as that variety; of the large grandiflora type per packet of 25 seeds s. d. 1 0

Earl of Plymouth.—Another charming variety of the "Spencer" type, practically a self buff, slightly suffused with rose, deepening as the flower ages to rosy buff, throwing a good percentage of fours; a grand exhibition flower ... per packet of 12 seeds 1 0

Mrs. R. M. Shelton.—This variety will be welcome on account of its vigorous habit, distinct colour, and invariably carrying four blooms on a stem right to the end of the season; colour, rosy carmine, slightly hooded, and as a garden variety is unsurpassed ... ... per packet of 25 seeds 1 0

Mrs. T. G. Baker.—One of the finest varieties of recent introduction. In the younger stages the flower is beautifully edged and tinted bronzy amber, but as the flower develops it becomes almost pure white; mostly four immense flowers of the decided "Countess" type, on splendid stems; makes a grand vase for exhibition per packet of 12 seeds 1 0

One packet of each of the above four varieties, **3s. 6d.**

No Sweet Pea grower should be without **Baker's List for 1909.** It contains many useful hints on successful growing, together with notes of interest to all enthusiasts; whilst the list of varieties embraces all the best of the new introductions. Sent post free on application.

GLADIOLI.

The great range and almost endless combinations of colour of the Gladiolus is hardly equalled by any other flower.

OUR HYBRIDS possess the most exquisite colourings, with blooms of exceptional size, and are borne on large and vigorous spikes, while so great is the diversity that purchasers of 100 corms will get but few duplicates. We consider them equal to any named sorts, and the cost is about one quarter.

WINNERS OF MANY AWARDS DURING 1908.

Our Illustrated Catalogue post free on application.

New Tomato "VICTOR."

This Tomato, the result of several years careful crossing and selecting, is, we have no hesitation in saying, the most prolific variety yet sent out. The fruit, which is of medium size, rich colour and splendid flavour, is borne in trusses of from 12 to 25 at every joint, and the plants are remarkably short-jointed. The flesh is wonderfully solid, and the seeds are few in number. Per packet, **1/-**

New Catalogue for 1909 Now Ready, Free on application.

DICKSON, BROWN & TAIT,
Corporation Street, MANCHESTER.

WE RECOMMEND

NITRIC DIET,

The Modern Soil Science Manure,

as being superior to other complete manures, and giving better results.

NITRIC DIET is a safe and lasting Manure of UNPRECEDENTED VALUE for Vines, Peaches, Carnations, Chrysanthemums, etc., and must not be confused with other productions bearing the title "Nitro" or "Nitrate."

Sold by Seedsmen in Tins at **6d.** and **1/-**. In Bags—7 lbs., **2/6**; 14 lbs., **4/6**; 28 lbs., **7/6**; 56 lbs., **12/6**; 1 cwt., **20/-**; or of the Sole Manufacturers—

R. J. BARNES & SON, MALVERN,

who will be glad to send Descriptive Booklet, also Current Prices of Bones and other Fertilizers.

NOTES OF THE WEEK.

Forests and Climate.

Since the question of afforestation, which means in most cases re-afforestation of areas which for one reason or another have been denuded of the trees which once covered them, is now coming prominently to the fore as an economical question of vital importance, it is not out of place to consider, as a side issue, the immense value of trees as a protection from rapid denudation of the land, and as a moderating factor of those extremes of temperature and humidity or drought which are apt to prevail in their absence. The enormous drain upon our forestal areas induced by human requirements for wood for constructive and manufacturing purposes, coupled in many parts of the world with an utter absence of any provision for maintaining the supply by replanting, has been found to have a very marked effect upon the climatal conditions of the areas concerned. In the first place, land covered by trees is protected from the direct baking action of the sun, and the consequent rapid evaporation of the rainfall. The rainfall itself is prevented from washing away the soil, since not only is direct impact prevented by the foliage, but the dense network of roots binds it together, the result being that every drop is absorbed. The bulk is utilised by the vegetation, and any surplus subsequently finds outlet by springs, which have only a denuding effect in the channels which they cut, and in the brooks, rivulets, and rivers which they eventually contribute to form. The moisture absorbed by the roots and transmitted as sap to the foliage, is largely returned to the atmosphere by transpiration, and in this way healthy local conditions are maintained, and Nature's operations are conducted on a gentle and gradual scale. Clear away the forest ruthlessly, expose the soil directly to the sun, and the smaller vegetation perishes to a large degree by exposure. The soil, deprived of its tenacity, due to strong interlacing roots, and directly exposed to the impact of the rain drops, is speedily worn into surface channels, so that the great bulk of the rainfall passes off immediately, especially as owing to the changed conditions it is apt to become torrential and spasmodic when it falls at all, the result being sudden floods alternating with periods of drought, induced by the absence of the natural moderating influence of vegetation. This is the case in rather dry and warm climates; in damp cool ones the result of forest denudation may be seen in the wide-extended peat bogs, such as we see in Ireland. These areas undoubtedly were once covered with forests, though why, and how the trees perished is not very clear. The familiar "bog oak," as black as ebony, is evidence that huge trees once existed where now dense masses of peat monopolise the surface. Local conditions, tending to a more or less waterlogged state of the soil, appear to have led up to a monopoly of the surface by spongy growths of mosses and other marsh plants to such an extent that, deprived of aerated soil by lack of drainage, the larger vegetation became ousted in the struggle, while, deprived of their binding root systems, and of the distributing influence of transpiration through arboreal foliage, the sodden, spongy, unstable conditions have increased to such an extent that catastrophic "bog slides" must occur every now and again, in default of any drainage artificially arranged to relieve the ever-increasing strain continuous growth involves. It is a curious fact that even in the hottest, driest, and sandiest deserts, such as those of Egypt and those of Arizona, the petrified remains of huge forest trees are found on the very surface as evidence of different climatal conditions at one time in their history. For the disappearance of such forests and the substitution of arid deserts we cannot account, but there is ample evidence that man himself is capable of effecting similar transformations, and has partly done so in many places, owing to an improvident felling of timber on a wholesale scale without any attempt to replace it by replanting. Fortunately, the results of such improvidence are now generally recognised, and common sense is being used in all civilised nations with a view to checking the evil.

MR. ROBERT ALLEN ROLFE, A.L.S.,
Of the Herbarium, Kew. The leading authority on Orchid Nomenclature.

Horticultural Exhibitions.

The season of horticultural exhibitions which commences within the next few days and terminates with the closing days of November, does not give promise of proving very eventful, but the programme is a full one, and there is ample justification for the hope that much useful work will be accomplished. One of the first of the competitive exhibitions is the hyacinth show that will be held under the auspices of the Royal Horticultural Society on March 9, and it should prove of much interest. Some years have elapsed since these attractive flowers have been shown in a high state of development in London, and the liberal prizes contributed by the Dutch Bulb Growers' Society should ensure a good competition. Especially interesting should be the contributions to the class for four pans containing ten bulbs of one variety in each, for this method of culture has not as yet been largely practised in this country. In Holland they are so grown extensively, and the large, finely developed specimens that one meets with at the spring shows are singularly effective. The competition for Mr. Robert Sydenham's prizes for hyacinths, tulips, and narcissi grown in moss-fibre or similar material should also prove of special interest, for this method of culture has much to recommend it in the preparation of bulbous plants for indoor decoration. It is simple enough, but the details must have careful attention to ensure a full measure of success. It is impossible to avoid a feeling of regret that the Royal Horticultural Society should have found it necessary to abandon its autumn fruit show, more especially as a change in plan from time to time might have sustained the interest in the displays of British-grown fruit. There does not appear to us any good reason why the show should be "every year practically a repetition of the previous year's show," with so great a wealth of fruit at command for the production of tasteful effect. We are, of course, fully aware that it is no easy task to maintain public interest in horticultural exhibitions. The magnificent exhibitions of the Royal Caledonian Horticultural Society suffered last year from public apathy. From the same cause the exhibitions of one of the principal societies in East Anglia suffered appreciably, and the Brighton Horticultural Society has found it necessary this year to limit its exhibitions to a rose show in July and a chrysanthemum show in November. We give these instances because in each case the exhibitions have been of the highest excellence, and the music provided has been good. At York in June, and at Shrewsbury in August, exhibitions of a high order of merit may be anticipated; that at York may not be quite equal to the jubilee celebration of last year, but it is safe to anticipate an exhibition fully equal to the high average that has obtained for many years past. The preparations that are being made for the celebration of the coming of age of the Cardiff Horticultural Society suggest that the exhibition, which will be held on July 21 and 22, will be in every way worthy of so important an occasion, and those who are acquainted with the work the society is doing will join with us in hoping the anticipations may be fully realised. The programme arranged by the National Chrysanthemum Society will, in the light of recent events, have to be very materially modified, with what results remains to be seen, for to hold the same number of exhibitions as in previous years is out of the question in the present state of its affairs. We have no desire to accentuate the difficulties of the situation that has been largely brought about by the adoption some years ago of a policy better adapted to a local, than a national society, and shall therefore not do more at the present time than express a hope that a means may be found for restoring the society to a sound position.

Mr. R. A. Rolfe, A.L.S., whose portrait we have pleasure in presenting to our readers in this issue, is probably best-known in the world of science and horticulture as the leading authority on orchid nomenclature. Mr. Rolfe entered service at Kew in 1879, and has remained there ever since. He joined the Herbarium staff in 1880, and at that time there was no one specially interested in orchids. He already had some knowledge of the order, and a strong liking for these interesting plants, consequently the herbarium work in connection with them fell increasingly to his share. It was natural he should early become interested in orchid hybrids, and he became convinced that many so-called species were but natural hybrids, and in his papers on "Odontoglossum Hybridisation from the Standpoint of Systematic Botany," and "Hybrid Cattleyas," he did much to clear up the origin of not a few orchids. In later times the hybridists have proved the correctness of Mr. Rolfe's views. Since the death of Reichenbach Mr. Rolfe has been recognised as the great orchid authority, but he has attained and holds that position by means of strenuous work. From its commencement he has edited "The Orchid Review," and he has been responsible for the orchids in the "Flora of Tropical Africa" and "Index Flora Sinensis." He has reviewed the Apostasiæ, a tribe of primitive orchids, and he has monographed the Vanillas. Quite recently—the book has just reached us—he has, in conjunction with Mr. C. C. Hurst, brought out the "Orchid Stud Book," a work of the greatest value to orchid hybridists, and one that represents an enormous amount of patient labour. Some years ago Mr. Rolfe was made an Associate of the Linnean Society, in recognition of his valuable work among orchids; he also has a seat on the Royal Horticultural Society's Scientific Committee.

Darwin Centenary Celebration. The following is the programme of the celebration of the centenary of the birth of Charles Darwin, which will take place at Cambridge, in June next. On Tuesday, June 22, there will be, from 8.30 p.m. to 11 p.m., a reception of delegates and other invited guests by the Chancellor of the University in the Fitzwilliam Museum. On Wednesday, June 23, there will be, at 10.30 a.m., a presentation of addresses by delegates in the Senate House; 4 p.m., garden party given by the Master and Fellows of Christ's College, in the college grounds; 7 p.m., banquet in the new examination hall. On Thursday, June 24, the honorary degrees will be conferred in the Senate House at 11 a.m., and the Rede lecture will be given in the Senate House by Sir Archibald Geikie, at noon. A Darwin exhibition will be held in Christ's College. The syndics of the University Press have agreed to present to each invited guest a copy of the first draft of "The Origin of Species," which is being prepared for press, and edited by Mr. Francis Darwin.

Visitors to Kew, 1908.—The number of persons who visited the Royal Botanic Gardens during the year 1908 was, according to the "Kew Bulletin," 2,710,220. These figures show a decrease of 252,494 visitors over the year 1907, when the number of visitors was the largest yet recorded. During the last ten years (1898-1907) 16,428,084 persons have visited the gardens, giving an average of 1,642,808. The total number on Sundays was 1,321,384 and on week-days 1,388,836. The number of visitors on Sundays is the largest on record, being in excess of that for 1907 by 52,883. The increase is probably very largely due to the great number of French visitors during the summer. The total number on week-days was 1,388,836, the corresponding number for 1907, 1,694,213. The maximum attendance on any one day was 98,388 on August 3. The smallest number on any one day was 68 on January 21. The greatest number on a Sunday was 70,904 on July 26, and is a record number for a Sunday, or an excess of 5,990 visitors over the figures for 1907. The smallest number on a Sunday was 1,032 on December 6.

New Open Space at Rotherhithe. A few days since the Mayor of Bermondsey opened the old churchyard attached to St. Mary's, Rotherhithe, as a recreation ground. The work has been carried out under the supervision of the borough engineer, and has given work for three months to 30 unemployed men. The ground is about half an acre in extent, and has been levelled, and laid out in paths, flower beds, and grass plots. The Metropolitan Gardens Association has presented seats, and, it is hoped, will shortly erect a drinking fountain.

Some Birmingham Gardens.—In continuance of our series of articles on district gardens, we shall give, in our issues of March 13 and March 20, accounts of numerous leading and interesting gardens in and around Birmingham. The accounts will be freely illustrated, and they will describe such well-known establishments as Edgbaston Botanic Gardens, Canon Hill Park, Whetstone, Whyddrington, Southfield, Berrow Court, Harborne Hall, Perry Hall, and Queen's Park.

State versus Private Forests.—With reference to the creation of large forest areas by the State, as compared with areas of moderate size in association with arable and meadow land, the well-known authority, Dr. Schlich writes: "Although the Commissioners appreciated my evidence on the great importance of combining field with forest work, they overlooked the fact that for this very reason afforestation by private proprietors should, as much as possible, be encouraged. The ideal solution of the problem is, not the creation of large extents of forests in one place, which would lead to a separation of field from forest work, but the establishment of fair-sized blocks scattered over the country. As long as each block is large enough to justify the employment of a man in charge of it, economic management is possible just as well, if not better, than on continuous large areas. The same labourers who work in the fields in summer can do the forest work in winter, without leaving their home. In the other case, they have to emigrate to forest colonies or whatever they are called. Moreover, by a proper distribution of the forest areas amongst cultivated areas, a local market for the smaller dimensions of timber and firewood would be created, whereas much of such produce would be of little or no value in concentrated large blocks of forest owing to the cost of haulage."

The National Horticultural Society of France has struck a special plaquette d'honneur in silver co morative of the recent retrospective santhemum show held in Paris. This the first show of the kind ever held, it is expected that it will not be the inasmuch as the co-operation of the bers brought together a remarkably esting collection of literary, histori artistic objects relating to the fa flower from the Far East. M. Rene M méja and Mr. Harman Payne, as the leading exhibitors, were awarded "plaquette commémorative."

Museum of British Forestry at Kew.—Cambridge Cottage, Kew, now, with its gardens, forming part of Kew Gardens, is, we understand, to be used as a Museum of British Forestry. This is good news, as also is it that Mr. William Dallimore, who has for several years been arboretum foreman at Kew, is to take charge of the new project, under Mr. J. Masters Hillier, the curator of the museums. Mr. Dallimore's long association with trees and shrubs began with the Messrs. Dicksons, at Chester, and at Kew he has had opportunities of studying timber from an economic point of view. Mr. Dallimore is a regular contributor to these columns, and we feel sure he will be as successful in his new position as in the one he has hitherto held, and which he relinquishes at the end of the present month. Mr. A. Osborne will be Mr. Dallimore's successor.

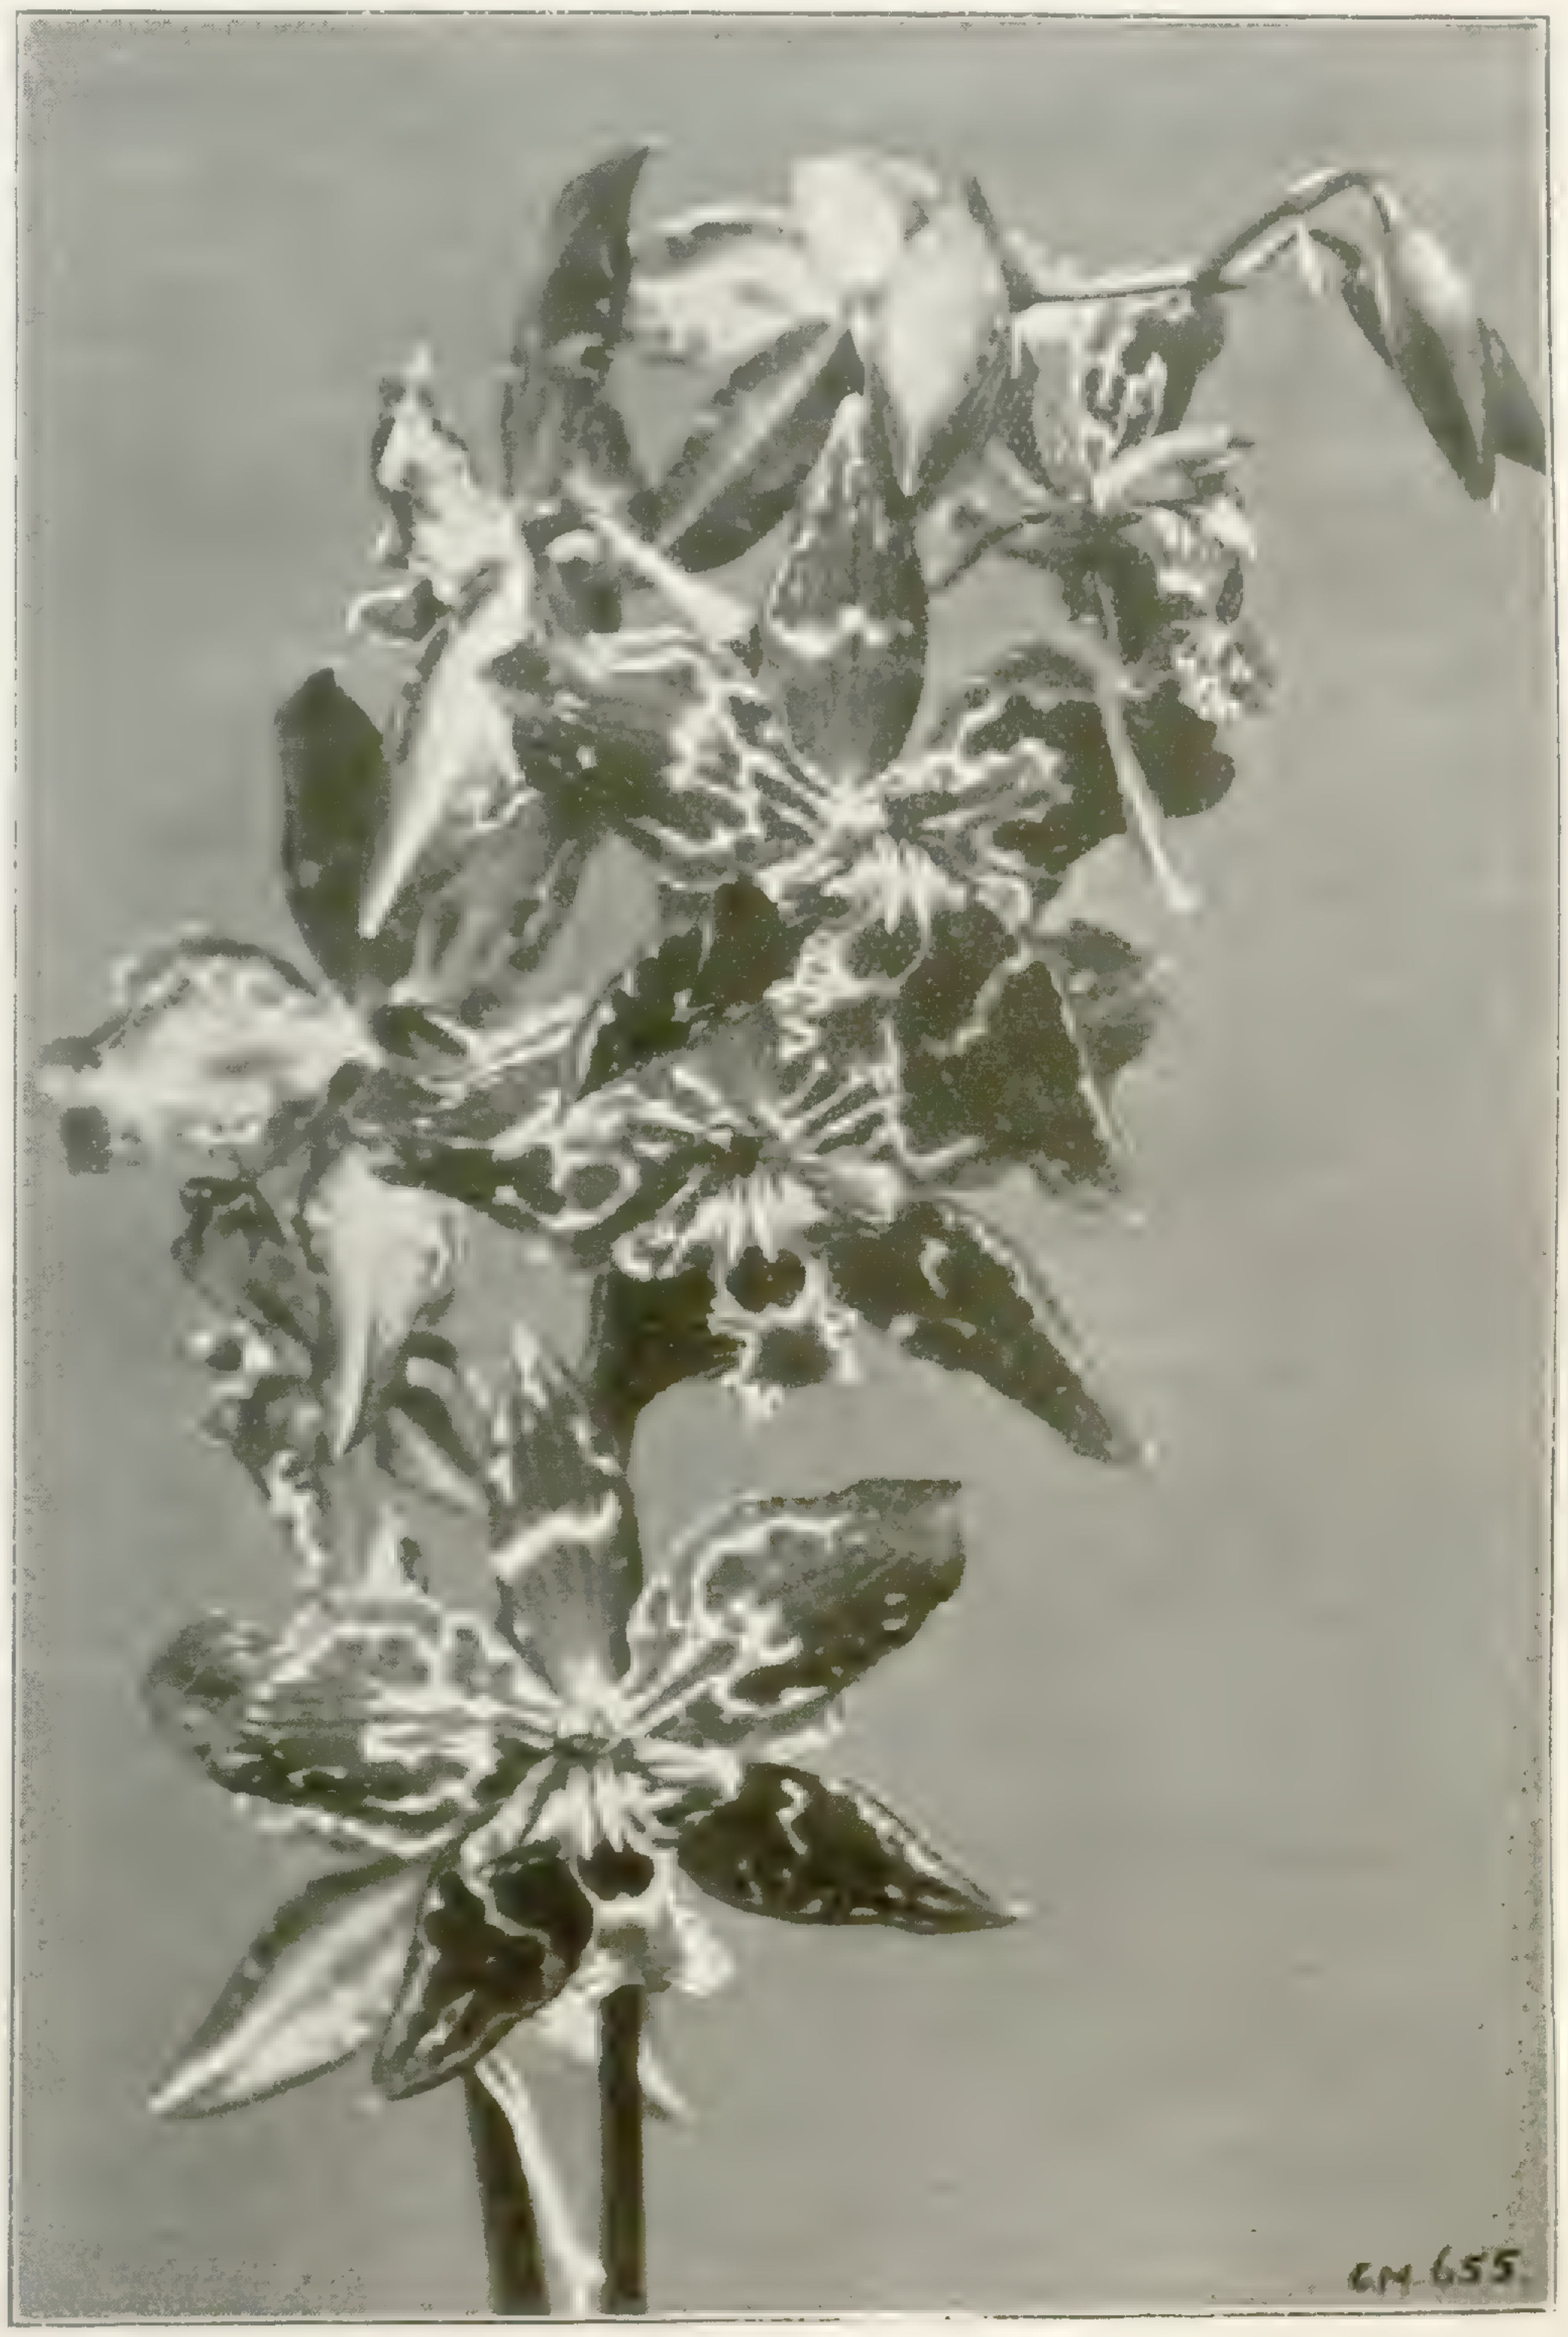
Mr. Charles Foster, so well known as Assistant Director of Horticulture at the University College, Reading, is to retire from that position for the purpose of establishing and directing a model farm at Sutton Place, Guildford, on behalf of Lord Northcliffe. Mr. Foster will not move from Reading until after midsummer, and he will carry out the sweet pea and other trials that are to be conducted in the college gardens.

Need of Observation in Rose Culture.—In a lecture on "Roses," given by the Rev. J. H. Pemberton before the Woodford Horticultural Society, this successful rosarian pointed out that to be a good rose grower one would have to cultivate the power of observation, and he suggested that a great deal might be learned from a close study of the growth and habit of the dog rose in the hedgerows. The lecturer gave excellent advice on pruning, culture, and pests, and he received a very cordial vote of thanks for his lecture.

Haarlem Jubilee Bulb Show.—The eighty-page schedule of the Jubilee Flower Show, to be held in Haarlem in 1910, is now published, and as it is in Dutch it will not prove very interesting to many. Competition is limited entirely to Dutch growers, and thus a fine opportunity of seeing what the various growers can do will be provided. There will be a permanent exhibition from March 23 to May 16, and, in addition to bulbs, it will include azaleas, rhododendrons, conifers, rock gardening, and herbaceous perennials. The first special show, on March 23-31, will be for bulbs, natural and retarded, forced shrubs, stove plants, etc., and the schedule consists of 275 classes. A second special show will be held on April 15-24; it will be of the same general character as the first, and will consist of about 300 classes. The third special show, on May 7-12, will be different to the others, and will probably be devoted chiefly to orchids, stove plants, and floral decorations. Every effort will be made to produce an exhibition that shall be a garden picture, and, judging from past efforts, this will be successfully accomplished. During the progress of the exhibition the Floral Committee of the Dutch Bulb Growers' Society will sit weekly to adjudicate upon new bulbous plants. Whether an international jury is to be invited to judge the exhibits, or whether the Dutch growers will make the awards, we do not know, but we expect the former method will be followed for several reasons, not the least of which is that it would attract a large number of people, and from different countries, and would materially enhance the commercial success of the undertaking. Our Dutch friends have been, and still are, having some practice in the arrangement of large scenically arranged flower shows, therefore we look forward to an unusually complete and striking display at Haarlem next year. At Noordwyk, and at Sassenheim good shows have been held in recent years, not to mention Haarlem itself, and this year there is the exhibition at Hillegom. The Jubilee Show should be a great affair.

Preservation of Leigh Woods, Bristol.—To prevent any misunderstanding that may have arisen in some minds as to what will be done with the Leigh Woods that constitute so great a part of the beauty of the Avon Gorge, at Bristol, Mr. James Baker, F.R.G.S., who has been a hard worker in the cause of preservation, writes: "The sylvan beauty of Leigh Woods and the remarkable example of a prehistoric camp have been rescued by Mr. G. A. Wills's munificent gift from destruction, not for the city of Bristol, but for the nation. The site is not to be presented to the public, nor is it to be used as a recreation ground by the populous quarters of that city, but it is to be handed over to a trust to be formed of nominees of the Gloucester and Somerset Archæological Societies, the Merchant Venturers of Bristol, the Kyrle Society of Bristol, and the Leigh Woods Land Company, to be kept for ever in its present primeval and idyllic state of woodland scenery, and the great camp to be left untouched. Certainly a recreation ground for all who love pastoral and forest scenery, but not for football pitches."

The Richmond Rose is in great favour in the great cut flower markets of Covent Garden, and elsewhere. Its deep red colour, beautiful form, and long stems, have made it a favourite with florists, and hundreds of fine blooms have changed hands for 1s. each. At present the greater part of the supply of this and other forced roses comes from Middlesex, from the Uxbridge and Hampton districts, smaller supplies coming from Hertfordshire and Kent.



ODONTIODA LUTETIA.

A charming new bigeneric hybrid, with a yellowish ground colour, freely marked with scarlet. F.C.C., R.H.S., February 23. Messrs. Charlesworth and Co., Haywards Heath.

L'Entente Cordiale.—At the annual dinner recently held to celebrate the twentieth anniversary of the Société Française d'Horticulture de Londres, when Sir Albert K. Rollit, Officer of the Legion of Honour, occupied the chair, a telegram was sent to M. Fallières, President of the French Republic, offering the respectful salutations of the members present. Sir Albert has recently received in reply a most cordial message from the Palais de l'Elysée, thanking himself, as chairman, M. George Schneider, and Mr. Harman Payne, Officers of the Mérite Agricole, and the rest of the company, for their kind message and salutations.

The Burbidge Memorial Library, instituted to keep in memory the life and work of the late Mr. F. W. Burbidge, now contains a considerable collection of books, but many more will be needed to make the library a first rate one. The librarian is Mr. Gunn, and the library is under the care of the Irish Gardeners' Association, at 7, Lower Sackville Street, Dublin.

Profitable Cropping.—An excellent example of the profitable utilisation of land in the production of vegetable crops is given by Mr. J. R. Dunston, principal of the Wye College, where intensive culture has been carried out with much success. In 1908 six acres of a field that had carried a crop of oats in the year previous was, on April 7, planted with potatoes, and of this area seven-eighths of an acre was devoted to first earlies. May Queen and Epicure were the varieties selected, and the tubers had been sprouted in boxes previous to planting. The land received a dressing of farmyard manure at the rate of 25 tons to the acre in the autumn, and was ploughed to a sufficient depth to bury the manure. In January it was deep ploughed, and three weeks subsequently dressed with a mixture consisting of 3 cwt. of superphosphate of lime, 1½ cwt. sulphate of potash, and 1½ cwt. of sulphate of ammonia. The cost of cultivating and marketing was £16 5s. per acre. The crop, which averaged 9 to 11 tons per acre, was sold at prices from 70s. to 90s. per ton, commencing July 7. The net return was £35 11s. per acre. Directly after digging, the land was ploughed, and cauliflower plants were put in, and well watered, with the result that there was no flagging, and they had a good start. The plants were put in at the rate of 10,000 per acre, at a cost of 4s. per 1,000 for plants. A hundredweight of nitrate of soda was given them, and they were hand-hoed once and horse-hoed twice. Selling began on October 28, when consignments were sent to the Borough Market, Bexhill, and some few were sold locally in Wye and Ashford. In all, 7,770 heads were marketed at an average price of 1.135d. per head, realising per acre £40 11s. 4d. The cost of the crop amounted to £10 per acre, so that there was a net return of over £30 per acre, which, with the return of the early potatoes, makes a total of over £49 per acre from the two crops.

Flower Imports.—The value of the flowers imported during January was £29,664, as compared with £29,180 in the first month of 1908, and £18,545 in the corresponding month of 1907.

Rare British Butterflies.—On Tuesday last Mr. Stevens commenced, at King Street, Covent Garden, the sale of the first portion of the collection of British butterflies formed by the late Mr. T. Maddison. The collection was very rich in rare and extinct species and remarkable varieties. Seventeen specimens of the large copper butterfly, which has long been extinct in Britain, were disposed of at prices ranging from £5 10s. to £1 5s.; but the best prices were made for the more remarkable varieties. A rayed form of Paphia, with the fore wings dark and suffused and the base and margin of underside of hind wings silvery, made £8; a variety of Aglaia, having on the hind wings broad dark bands, from which rays extend to the margin (from the Linnaean collection), £9 10s.; a tawny orange variety of Euphrosyne, £9; an Athalia, obscure, with central band of pale spots on underside of hind wings, £9; Polychloros, with irrorated margin and the costal blotches united, £7 10s.; a very fine dark variety of Iris, £7; a magnificent variety of Tithonus (figured in the "Entomologist" for October, 1907), £8 10s.; and a golden-brown male of Tithonus, £6.

National Rose Society.—The membership of this society continues to increase at a rapid rate, 193 names having been added to the list since the annual meeting in December last.

Employees in Public Parks who intend presenting themselves for examination by the Royal Horticultural Society next year, should carefully consider the views of the examiners at the recent examination, as expressed in their report: "There is still much room for improvement, the higher standard hoped for in last year's report having to be still held in anticipation. A completer knowledge of garden practice and the reasons for it; the values of phosphatic and nitrogenous manures, their comparative cost, and the quantities required; the art of curves and the power to express them neatly on paper; arithmetical calculations for land measures and simple cash computations—such things as these, added to a more intensive knowledge of gardening specialised for public parks, are necessary to raise the employees to the standard of really first-class craftsmen whose skill is to find expression in the gardens which they serve. The higher places gained by most of the old candidates in the lists should be an encouragement to the less successful to persevere diligently with their work, and try again next year." Having duly considered these views, they should at once commence the work of preparation. Especially should they be careful to fully exercise their powers of observation in the course of their ordinary duties, for knowledge so gained will stand them in good stead when in the examining room.

Aerial Roots in Acanthoriza aculeata.—An interesting communication relating to the aerial roots of this palm was made by Miss Bertha Chandler, M.A., B.Sc., to the monthly meeting of the Edinburgh Botanical Society. It was pointed out that these roots differ from normal aerial roots in their life history, for they become metamorphosed from simple roots provided with a root-cap to hard woody thorns without root-cap. The most interesting point to notice about these aerial roots, however, is their function. It is considered that in their early existence they act as pneumathodes or breathing roots, an inference drawn from the presence of much air-tissue. This function persists even in the thorn stage to some extent, but with the loss of aerenchyma, the root-cap, and the hardening of tissues, the function becomes largely that of protection. The fact also that many of these roots do not develop as thorns, but on entering the ground become normal roots, adds a third function to those already mentioned, one similar to that of the prop-roots of the screw pines.

Sandringham Horticultural Society will, by permission of the King, hold its annual exhibition in Sandringham Park on Wednesday, July 21.

Mr. W. B. Hemsley, F.R.S.—As announced in these pages, Mr. Hemsley retired at the close of last year from the position he occupied as Keeper of the Herbarium, Kew. We have now the pleasure of stating that, in certifying that Mr. Hemsley has discharged his official duties with diligence and fidelity and to their entire satisfaction, the Board of Agriculture and Fisheries placed on record "their appreciation of the very valuable services which Mr. Hemsley has rendered to the Royal Botanic Gardens at Kew since he became associated with that institution, now nearly 49 years ago. His constant courtesy and kindness to his colleagues, the ability which he has brought to the discharge of his duties, and his high scientific attainments have all contributed materially to the maintenance and development of the distinguished reputation which Kew enjoys both at home and abroad. The Board greatly regret that Mr. Hemsley's retirement has become necessary, but they trust that he will be spared for many years to come to continue his labours on behalf of that science with which his name is so honourably associated and towards the prosecution of which he has done so much."

Phenological Observations, 1908.—At the recent monthly meeting of the Royal Meteorological Society, Mr. E. Mawley read his "Report on the Phenological Observations for 1908." He said that the most noteworthy features of the weather of the phenological year ended November, 1908, were the severe frosts early in January, the exceptionally heavy fall of snow and remarkably low temperatures in the latter part of April, and the marked periods of unusually wet and dry weather during the summer. In February and March wild plants came into blossom in advance of their usual time, but throughout the rest of the flowering season were more or less behind their average dates. Such early spring migrants as the swallow, cuckoo, and nightingale made their appearance very late. The only deficient farm crop was barley. The yield of wheat, oats, and beans was rather above the average, that of peas and hay very good, while the crops of turnips, mangels, and potatoes taken together were the most abundant for many years. The yield of apples was under the average and that of pears and plums much under the average. On the other hand, the crops of currants, gooseberries, and strawberries were almost everywhere unusually good. As regards the farm crops this was the third good year in succession, although compared with 1906 and 1907, the yields in 1908, except in the case of turnips, mangels, and potatoes, were very inferior to those of either of the years mentioned.

Rose Pavilions are of many kinds, and not always well adapted to the purpose which they are intended to serve. There has been a marked improvement in them of late years, and the heavy and highly ornate structures which at one time enjoyed considerable popularity no longer find favour either with manufacturers or owners of gardens. Lightness and simplicity of treatment are considered essential, and properly so, for the object of the rose pavilion is not the display of the skill of the worker in iron, but to support roses of scandent habit in such manner as to display their charms to the best advantage. The pavilion which contributes so liberally to the attractions of the rose garden at Woburn Place, Addlestone, the residence of E. A. Mocatta, Esq., happily combines elegance with simplicity, and may well serve as an example of what such structures should be. It will be seen that the several sections are of a sufficient height and width to enable anyone to pass through them without the inconvenience and discomfort inseparable from spaces of small size. The illustration is also of interest as evidence of Mr. T. Stevenson's skill in the cultivation of roses.

Interesting Plants.—At the recent meeting of the Linnean Society, at Burlington House, the Rev. E. S. Marshall exhibited some interesting British plants. These were a hybrid saxifrage (Saxifraga nivalis x S. stellaris), found on Cairngorm, quite intermediate in character between the parent species; a new orchis, allied to the male orchis; a hybrid rock rose (Helianthemum chamaecistus x H. polifolium), a good intermediate, and apparently quite fertile form; and two hawkweeds (Hieracium hyparcticum and H. eustales) from Sutherlandshire, a new locality for them. At the same meeting Professor Weiss showed specimens of a tropical fresh water alga from the canal near Stockport, at the part where the water is warmed by the inflow from the cotton mills. Sub-tropical aquatic plants have also been found at the same part of the canal. They are supposed to have been introduced with refuse from the cotton mills.

anxious to make this section a special feature this year, and feel that the realisation of their desire can be best accomplished by the hearty co-operation of Southern confreres English and Scottish.

British Association Meeting. The meeting of the British Association will, as previously announced in these pages, be held at Winnipeg, in August next, under the presidency of Sir J. J. Thomson, F.R.S. Arrangements for the meeting are already being made, and a local Executive Committee, with officers, have been appointed to organise excursions to places of interest and assist visitors generally. Owing to August being the busiest month of the year in the bookings to America and Canada, no reduction in the steamship rates will be made to members, but they may be given superior accommodation on the return voyage at the ordinary minimum rate. The journey to and from Winnipeg and the meeting will occupy about thirty-two days. The estimated personal expenditure of each member attending the meeting is a minimum of £38, and an average of about £65. If the excursion to the Pacific Coast is taken the additional expense will be £25.

Cascara sagrada, the drug so largely used for medicinal purposes, is furnished by the bark of Rhamnus Purshiana and R. californica, natives of Western North America. The drug was introduced into medicine about thirty years ago, and since that time the wild source of supply has been rapidly depleted. Some years ago seeds were obtained for Kew, and plants raised and planted in the Royal Gardens, and from the way in which R. Purshiana has flourished at Kew it seems not unlikely that it may be a suitable subject for introduction to the western coasts of the British Islands, and may also prove to be of value commercially, since the local supply is becoming exhausted, and plantations do not appear to have been started in America. The Kew trees withstood the severe frosts of February, 1895, without protection. In order to test whether the bark of an English-grown tree would yield the drug in the same percentage, and of as good a quality as that of the native samples, one of the Kew trees was cut down for purposes of analysis. Messrs. Burroughs, Wellcome, and Co. very kindly undertook to examine the bark and to report the results of their investigation, and 5¾lb. of dry bark, the produce of the Kew tree, was sent in February last to Dr. H. A. D. Jowett, senior chemist of the Wellcome Research Laboratories, London, for analysis. The bark sent was duly worked up into tabloids—some of which are now in Museum No. 1—and it has been reported that "the present extract is undistinguishable in its action from that made from American bark," and in a further letter from Messrs. Burroughs, Wellcome, and Co., it is stated that "The physician, to whom your special cascara was submitted, reported it to be equal to the average of tabloid products from bark grown in America." An illustration of one of the Kew trees, together with an account of the chemistry of the bark, is given in the current issue of the "Kew Bulletin."

THE ROSE PAVILION AT WOBURN PLACE, ADDLESTONE, THE RESIDENCE OF E. A. MOCATTA, ESQ. (See page 160.)

Aberdeen Horticultural Society.—This society has just issued its prize schedule for the annual exhibition, to be held on Thursday, Friday, and Saturday, August 19, 20, and 21, 1909, in the Duthie Public Park, Aberdeen, the exclusive use of which for the three days has again been generously granted by the City Council. There are the usual four divisions—professional gardeners, nurserymen and florists, amateurs, and working men. Among the prizes offered are two magnificent silver challenge cups and sixteen silver medals, while the prizes in money are very liberal indeed. Although a goodly number of exhibitors from the South invariably put in an appearance at the society's shows, it is felt that there is much room for extension in this direction, and especially in the section devoted to pot plants. Several of the directors are

THE NEWER PERPETUAL CARNATIONS.

Especially noteworthy among the newer perpetual-flowering carnations exhibited at the recent exhibition of the Perpetual-flowering Carnation Society, was the lovely Rose Doree, from Mr. Lancashire, of Guernsey, a sterling rosy-hued gem, which I had previously remarked upon. From the same grower came the new white Empress, a beautiful variety, which is lightly marked with pink.

Afterglow, the glorious rosy-cerise American, is a prominent variety, and when it is brought more into general cultivation will certainly have to be reckoned with. Victory maintains its good character, and when under good cultivation few carnations can surpass it for size, vigour, and colouring. That sterling fancy variety Imperial is undoubtedly the best of its section, and should meet with general approval, though fancy varieties are not to be compared to selfs in the race for popularity.

PERPETUAL FLOWERING CARNATION, WINSOR.
A lovely variety with large flowers, the colour bright silvery pink, shown by Messrs. Hugh Low and Co., at the Royal Horticultural Hall.

Winsor, with its clear silvery-pink colour, continues to advance in favour, and will for long hold high rank in its class. It is both vigorous and free flowering, and the blossoms are distinctly fine. Winona is another sterling acquisition from that expert American raiser Mr. F. Dorner. In colour it is a taking salmon-pink, and will prove a strong rival to Mrs. H. Burnett. Winona is a very fragrant variety, and with a good habit and a pleasing formation, it should find a place in many collections.

There are other newer varieties of merit, which, perhaps, do not loom so largely in the public eye, yet one would fain advocate their merits, and press their claims for a fair trial. Among these I would again note Andrew Carnegie, the scarlet Harlowarden, as I describe it. This bright scarlet, with the form, fragrance, and floriferous character of the latter sterling crimson variety, should be in great demand where continuous supplies of scarlet flowers are required. Beacon, with its earliness and freedom, both in growth and blossom, is a first-rate scarlet. The form is good, and a batch of plants should throw more blossoms than most of the older varieties. Defiance is another good clear scarlet, bright in appearance, with strong stems, and faultless blossoms of good size.

Two richly-coloured varieties, which seem to be at their best when utilised for winter flowering, are Red Chief, a rich bright red; and the deep scarlet Red Riding Hood, a long-stemmed robust variety. Of the whites Lady Bountiful and White Perfection keep well to the forefront. One would like to see more of White Enchantress, but there is a good deal of difference between the white sports of Enchantress as they have occurred with different growers, though in its best form it is undoubtedly a good carnation. The new white Sarah A. Hill comes with excellent credentials. It is of the true American type, with fringed petals, and it is of large size, bold, and free. One sees far too little of that good white My Maryland, but when well grown it is certainly a sterling variety, clear in hue, and of good size.

A coming crimson is Harvard, a richly-coloured gem, which has the good qualities of freedom, size, and strong stems. Dorothy Whitney is a useful yellow fancy, lightly edged and marked with pink. Being both early and free, and possessing a good habit, it should be included in collections, for yellow varieties are still scarce.

In spite of a love in some quarters for heliotrope-coloured carnations, there is a scarcity of varieties of this colour. The best, so far, seems to be Mikado, a good variety of a true glistening heliotrope shade. Mauve Queen is lighter in hue, of good size, and very fragrant. The new pink Mabelle should be given a trial; it is undoubtedly a good carnation, and the enquiries for it in the retail trade in the States testify to its pleasing colouring and good form. It is strong in growth, fragrant, and free.

The two lovely sports from Enchantress seem bound to have as good a career as their famous parent. Rose Pink Enchantress is a grand rosy-hued variety, good at all points, while Helen M. Gould is equally fine, and the colouring is a delightful shade of clear pink with carmine markings.

The Lawson sports seem to be dropping in favour, though the type Mrs. T. W. Lawson continues its triumphant progress. White Lawson has been seen less of late, but the newer Melody, a non-fading light pink, with all the good points of its parent, should prove a serviceable variety. The other newer sport Salmon Lawson, which originated as a sport from White Lawson, has hardly received so wide a trial as one would expect, but it may yet come more to the front; but the older sports, Red Lawson, Variegated Lawson, etc., are declining rapidly.

Aristocrat should find many supporters, being a first-rate variety, lighter in colour than Mrs. Lawson, and continuous in flowering. Other carnations that are keeping well to the front are Britannia, Fair Maid, Prosperity, Floriana, Flamingo, Crimson Glow, President, and Nelson Fisher. The pink sport of Imperial has not done quite so well as was expected, but further trial will perhaps give better results.

With the ever-increasing patronage which the perpetual carnations are receiving, their success in the future seems well assured.

P. S. HAYWARD.

American Gooseberry Mildew in Kent.—We are informed that 2,010 acres of gooseberry plantations in the county of Kent have been infected with American gooseberry mildew. Of this number 108 acres have been grubbed by the owners voluntarily and without compensation, and 1,500 acres have been pruned to the satisfaction of the inspectors

MELONS.

During the summer months well-grown and perfectly ripened melons are much appreciated, as they form a cool and refreshing dessert. It is, however, not until the latter end of April or early in May that the sun is sufficiently powerful in this country to give the fruit its finest flavour; for without sun and air, even though the requisite artificial heat be maintained for their growth, there will be lacking that lusciousness that would otherwise be present. The reason many people do not care for melons is, doubtless, because they have had ill-ripened fruits. A melon may, to outward appearance, be all that one could desire, but when one comes to taste it there may be great disappointment, the flavour being little, if anything, better than that of the Spanish water-melons sent in such quantities to this country.

One has often heard the remark passed that there is much difficulty in procuring a finely-flavoured melon from a fruiterers' shop. This, in a measure, is not difficult to understand, for like all other fruits of such a perishable class, they must be cut before being fully ripe, when sent to market. For a melon to attain its full flavour it should be allowed to remain on the plant until the juice begins to ooze out round the stem, as a rule it is then at its best.

For a first crop the seed should be sown about the second week in January. If a slight hotbed can be made in a house where the temperature can be maintained from 60 to 70 degrees, this will be favourable to germination. Prepare some three-inch pots by filling them with turfy loam that has been pulled to pieces and thoroughly examined to see there are no wireworms in it. Place one seed in the centre of each pot, point downwards, and cover with about an inch of soil, then plunge in the hotbed if this is not warmer than 80 degrees. If the temperature of the bed is higher than this, stand the pots on the surface until the heat has abated somewhat. To some this may seem unnecessary trouble, but herein, in a measure, lies the secret of obtaining strong plants to start with. By inserting the seeds thus, the seed leaves are freed from the husk, and the base of the plant is deep enough in the soil to support it in an upright position. If the requisite temperature is maintained the plants will be large enough in about three weeks to be transferred to their permanent quarters; therefore, in order to avoid any check in their growth, preparations should be made accordingly. Though we have hot water pipes running underneath the melon beds, we always make up a hotbed of fermenting material from eighteen inches to two feet in depth. This serves the double purpose of generating a moist heat to give the plants a good start, and providing something for them to feed on during the time the fruit is swelling.

Over the surface of this hotbed a layer of sods is placed with the grassy side downwards. We are not at all particular as to whether they are newly cut or not, for often they are brought in fresh from the park and used straight away. A ridge of the same material, about a foot thick, but chopped to pieces with a spade, is placed over the sods as near to the front of the house as possible. Though our soil is a stiff loam bordering on clay, this is rammed until it is made quite firm. A few pieces of carrots are then inserted in the soil at intervals of about two feet or less. In the course of a few days, owing to the heat of the fermenting material beneath, if there are any wireworms in the soil they will be driven to the surface of the ridge and will commence to feed on the carrots. If these are examined every morning for a week or so the soil may be rid of these troublesome pests. By this time the bed will be in a condition to receive the plants. We plant about two feet apart on the top of the ridge, growing them, as a rule, on the single rod system; but should there be any extra strong growing kinds these are pinched at the third or fourth joint, and two canes taken up on each plant. If the weather is favourable, so as to run up the temperature of the house to 90 or 100 degrees in the day time, the plants will make rapid progress, but, if the weather is dull, then care must be taken both in watering and syringing, otherwise the plants, having but few roots, are apt to damp off.

MELON NEW MASTERPIECE.

A fine scarlet-fleshed variety, raised by Messrs. E. Webb and Sons.

Great care is necessary in syringing, for the spray from the syringe, if of great force, is apt to twist the stems on one side, and should this occur to any serious extent, it causes them to split, which is a sure source of canker. To avoid this, see that not only the leading shoots, but the leaf-stalks also are secured to the wires to prevent them from twisting, until the lateral growths are of sufficient length to be secured in their places. There is a great diversity of opinion about pinching these laterals, but we always pinch at the first joint beyond the fruit blossom as soon as this can be seen, so that by the time the female flowers are developed, the leaf beyond is sufficiently advanced to cause the sap to flow freely. Again, some advocate allowing the growths to advance until so many flowers are available for impregnation at the same time, but in this we differ, for as the flowers open they are fertilised, whether there be one or half a dozen open at the same time, and the crop is regulated by thinning the fruits after they have started to swell. By the time the last flowers are fertilised, those that were set first have fruit half grown. This doubtless is at variance with the practice of some growers, but if those who have not hitherto watched the swelling of the fruit closely will take the trouble to do so, they will soon be able to observe when the seeds are forming, for at that stage swelling ceases for a time, so that if any flowers are fertilised at this period the fruits are sure to swell very rapidly, and if these are situated on the upper portion of the plants they usually grow to the largest specimens.

During the growing season the plants should be liberally supplied with water at the roots, and daily syringed to keep the foliage clean. By the time the fruit has grown to half its size a top dressing will be needed. This should consist of chopped turf and lime rubble, rammed firm. Liquid manure is also beneficial, but this should not be allowed to come in contact with the stems. Beyond this, and keeping the laterals pinched as they appear, very little more attention is needed. To prevent woodlice from eating the stems round their base, put a handful or two of newly slacked lime round them, so that this covers the bine for about two inches up. This will not injure the plants in the least, provided it has been slacked for a couple or three days previously to being used.

It has often been advised that, to have good melons, plants should carry from only four to six fruits each, according to the size of the variety. Much, however, depends on how the plants are treated. Where some growers would only be able to produce four or five good fruits, others would secure from ten to a dozen of first-class quality. The year the variety Windsor Castle was introduced I had one plant that carried ten fruits, averaging 9¼lb. each, and from this one may judge the enormous quantity of plant food required to bring those to a state of perfection. Yet when the fruit was ripe the foliage was as green as when the plants were in active growth. New Masterpiece is a free cropping scarlet fleshed melon, of fine quality, and it is a good grower.

Having grown the majority of varieties that have been introduced during the last 25 years, many of them before they were placed on the market, one may judge that a great number have passed through my hands. The largest fruit I ever grew was 12½lb.; this was one of four on the same plant. It is difficult to advise which are the best varieties to grow, as there are so many really good ones, and new varieties are introduced each season in such numbers that it is a hard matter to keep pace with them. Those who have to keep up a constant supply from early in the season until late in the autumn find it an advantage to grow several varieties, as some will ripen fully a month sooner than others, even when planted at the same time and in the same house.

Melons may be successfully grown in frames, but it is difficult to give them the same attention there as in properly constructed houses, but where it is absolutely necessary to grow them thus, a hotbed should be made up in April for the first batch, and good strong plants should be put out then, and liberally treated as previously recommended for plants in houses, with the exception that it will be necessary to take out the point of the leading shoot when it has attained a length of about six inches, so as to induce as many laterals as possible. These should be so regulated that the growths may fill the frame as quickly as possible. Fertilise the flowers, when dry, in the middle of the day, when the pollen is dry, and during the time the fruit is swelling maintain a temperature from 70 to 80 degrees during the day, and to prevent it from falling too low at nights cover the glass with mats or other protecting material. When the fruits have done swelling, give a little more air, but less water at the roots, which will improve their flavour.

EFFECTIVE BORDERS OF HERBACEOUS PHLOXES AT HEMINGFORD GREY, ST. IVES, HUNTS.

ADVANCES IN HERBACEOUS PHLOXES.

Within recent years a considerable number of ornamental plants suitable for beautifying the flower garden have been materially improved as the result of well-directed effort and persistent endeavour; but it is doubtful whether the advance has in any case been more marked than may be seen in the herbaceous phloxes. The high degree of development to which these attractively coloured and delightfully fragrant flowers have attained is all the more remarkable from the fact that of late but little has been heard of the progress that was being made. From twenty to thirty years since, considerable attention was devoted by raisers in this country to the production of new forms, and the success achieved was so great that the most meritorious of the varieties introduced were for the most part of home growth. The raisers in Great Britain were especially successful in the development of the spike and increasing the size, and improving the form of the flowers, but they do not appear to have taken full advantage of their opportunities for extending the range of colours. After a time there was a relaxation in the endeavour that was in this country being made to increase the usefulness of the herbaceous phloxes, owing, among other causes, to the death of two or three of the raisers. Coincident therewith the work was entered into with greater spirit by Continental raisers, and as they appear to have taken the finest of the British raised varieties as their standard for the form and size, a considerable proportion of the more recent of the Continental varieties have possessed much merit. More attention appears to have been devoted on the Continent to the development of new colours than at home, and as the result there are numerous colours at once distinct and beautiful. On the other hand, there is a considerable number with flowers that, with age and also under the influence of bright sunlight, pass to an ineffective slaty hue, which is far from pleasing. Few, indeed, are the home-raised varieties that have this effect, and it is a matter of considerable interest that during the past few years raisers in Great Britain have paid special attention to colour variation without losing sight of the essentials of form and size.

The cultivation of these phloxes is less difficult under the cool, moist conditions that obtain in the midland and northern counties of England, and in Scotland, than in the southern counties of England. But under good cultivation they can be grown to a high degree of perfection in any part of the United Kingdom. This, briefly stated, consists in providing a deep root run and a plentiful supply of plant food. In other words a liberal dressing of moderately well rotted manure from the farmyard or stable should be spread over the surface of the bed or border and the soil be then broken up to a depth of eighteen inches, or two feet, and the manure be well incorporated as the digging or trenching proceeds. A mulch of partly decayed manure or other loose material during the spring and summer months will be highly beneficial in checking evaporation, as also will be several thorough soakings of water during periods of dry weather.

Increase of stock may be effected by means of cuttings or division, and, as the old plants should not remain in beds and borders more than three years, a few young ones should be raised annually. Propagation by means of cuttings is strongly recommended by many successful cultivators, and the method has much to recommend it, especially to those who are desirous of producing spikes suitable for exhibition. Spring is the best season for rooting the cuttings, which are taken when the new growths are four or five inches high. The tops are taken off about three inches below the apex, and cut immediately below a joint. The lower leaves are removed, and the cuttings inserted, singly or two or three together, in small pots filled with light sandy soil. They should be placed in a frame where they can be kept warm, close, and shaded until rooted, and when this stage has been reached they must be gradually hardened off and eventually placed in an unheated frame. Towards the end of May or early in June, they should be transferred to a nursery bed in an open position, and arranged twelve inches apart in rows with eighteen inch spaces between them. In the autumn, when the growths are dying down, they must be lifted and planted where they are intended to bloom.

Division is a very simple matter, and well adapted to the requirements of those who grow these flowers for flower garden decoration. Early in the year when the growths are just appearing above the surface, the plants are lifted and portions consisting of three or four healthy shoots taken off with their roots from the outside. These are replanted at once in a fresh position, and in the ordinary course produce fully-developed spikes at the usual season. If the division and replanting is carefully and smartly done the replanted portions will not feel any appreciable check. No part of the central portion of the old plants should be replanted, and in the second and subsequent years the growths should be thinned to three or four shoots each. If large blocks of one colour are required in mixed borders, three plants of one variety should be planted in the form of a triangle with two feet sides. Phloxes are very effective arranged in this way, and borders wholly devoted to them, as so admirably depicted in the illustration given herewith, are highly attractive and of much interest.

With so large a number of fine varieties to select from, it is not easy to make small selections. The following are all of a high degree of excellence: Ary Scheffer, rich salmon, with crimson-purple eye; Boule de Feu, scarlet; Charles Pfitser, pink, white centre; Coquelicot, orange-scarlet; D. T. Laird, rose-lilac, purple eye; Emile Duclaux, white, large purple centre; Etienne Laury, salmon, deep red eye; Felix Dantee, magenta; Fiancée, pure white; General Van Heutsz, bright salmon, white centre; Glendarnel, rose-pink, light centre; Gruppen Konigin, bright pink, carmine centre; Henry Fouquier, rose, crimson centre; Hermann Ostertag, deep scarlet, crimson centre; John Forbes, rich pink, crimson centre; Lady Nina Balfour, rose-pink, deeper centre; Liberté, salmon, red centre; Louise Abbema, cream-white; Marchioness of Linlithgow, salmon, red centre; Montoguard, deep rose; Paul Bert, lilac, purple centre; Robert Pringle, rose, suffused salmon, rose centre; Tapis Blanc, pure white, dwarf; Thomas Hay, rose-pink, crimson centre; Von Lassberg, pure white; and Violet. The last-named is a new and distinct variety, remarkable for the large size of the spike and flowers and for its lustrous violet hue. It was well shown at the Royal Horticultural Hall last season by Messrs. Gunn and Sons. G. G.

G.M. 496

NEW HERBACEOUS PHLOX VIOLET.

A handsome variety with deep violet coloured flowers, exhibited by Messrs. Gunn and Sons at R.H.S. Meeting, September 1, 1908, and granted an Award of Merit.

THE ALPINE LADY'S MANTLE.

There are some people who despise our native alpines, and who rigorously exclude them from their gardens, but these suffer a deprivation, indeed, when they have not included among their treasures such charming plants as our Alpine Lady's Mantle, Alchemilla alpina. There are, it is true, many plants with more showy flowers—for those of this alchemilla are only greenish, but they are pretty to examine. On the other hand there are few of our exotic alpines which can compare in beauty of foliage when examined with this plant, although even this charm is not obtrusively displayed, but is studiously concealed from the passer-by. The prettily formed leaves are of a pleasing green above, it is true, but they would be passed unobserved save by those who study beauty of foliar development. But, if these leaves are turned up, their high beauty is realised, as they are of the most beautiful silky texture, and are all silver-like as well in appearance. It is not easy to convey in words any indication of this silvery, silky under surface, but it is so beautiful that those who know the Alpine Lady's Mantle can hardly pass it without turning up its leaves to admire their beauty.

Although a native of the mountains, this plant will flourish readily on a rockery in the lowlands, and even there it does not appear to be troublesome in its requirements, as I have cultivated it successfully in both dry and moist rockeries, and in full sun as well as in half shade. It is perfectly hardy, grows freely to a height of about six inches, and is easily increased by means of division or by seeds. Sometimes self-sown seedlings will appear close to old plants, and these may be removed any time during the year. S. ARNOTT.

Everyone interested in a garden should obtain a copy of the ALPHABET OF GARDENING, by T. W. Sanders. Thoroughly practical information is given as to soils, manures, seed sowing, planting, potting, budding, pruning, grafting, forcing, hybridising, etc., with explanatory diagrams. Price 1s. 6d. net, by post 1s. 9d.; cloth, 2s., by post 2s. 3d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

THE GLADIOLUS.

The gladiolus is one of the most noble of our autumnal flowers, and one comparatively neglected by many. There is no flowering plant so well calculated to improve the aspect of the garden in autumn, no matter what its style. One may also safely say the gladiolus is the finest of all flowers for indoor decoration in autumn, its tall and noble spike entirely preventing it from being used to produce the dumpling-like effects given by dahlias and other popular flowers.

But its value in the open air is even greater; nothing in the way of a flowering plant will prove so good for varying and giving a more graceful and bold character to the flower garden. One fact, however, should not be lost sight of, i.e., that in all cases, either a naturally sandy, rich, and deep soil should be given it, or one made so artificially. There are many stiff and sticky soils on which it would be much better to avoid gladiolus culture and turn one's attention to things more tolerant of the soil. But the question of soil once settled, let us take the case of a bed of choice roses in some position near the house. Most probably this bed will present a somewhat disappointing aspect after the roses are past their best, and even if they continue to flower well, the peeping forth of some splendid spikes of gladioli here and there will surely not detract from their beauty! Now, to secure this most desirable end, all we have to do is to insert some bulbs of the various kinds of gladioli in the spaces between the roses in the early part of May, or thereabouts. Plant them singly here and there, and at about three or four inches deep.

A BEAUTIFUL FORM OF GLADIOLUS KELWAYI.
A distinct type, including many fine varieties raised by Messrs. Kelway and Sons.

Need it be noted how tastefully they may be introduced just within the edge of the low, choice shrubbery, or beds of valuable shrubs on the lawn? Groups of them in the centre of flower beds would be splendid, and planted thinly here and there among beds of low-growing plants like say saponaria, mignonette, etc., they would rise above these, and their effect above the surfacing flower would prove very fine indeed. They may be placed in groups or rings around standard roses, they will make most valuable groups in the mixed border, or they make grand beds of themselves, or associated with lilies.

Where gladioli are grown in some quantity, it is, of course, best to give them a position on a border in the kitchen garden, as the formal aspect of anything grown in quantity is not nice for the lawn, pleasure ground, or flower garden. The varieties are legion, and many of the most beautiful varieties are now offered by the trade at very cheap rates.

All lovers of the gladioli are deeply indebted to Messrs. Kelway and Son, of Langport, for the many exquisite varieties introduced by them within the last few years. The following should find a place in every collection: Countess Crewe, a charming variety, white, shaded pink; Leader, a pure yellow with bright orange centre; Marks Barn, rosy crimson, flaked and shaded with maroon; Mrs. H. Cornwallis West, mauve, white spot, very handsome; W. Newcombe, flesh, flaked with light centre; Benjamin Harrison, orange-cerise, very large and useful. T. B. Field.

Ashwellthorpe Gardens.

CLEMATIS CALYCINA.

Although this clematis is less ornamental than many other species, it is sufficiently interesting to warrant its inclusion in gardens where out-of-the-way plants are encouraged. Its chief interest centres in the fact of the flowers being produced in mid-winter, a condition shared by one other hardy species, C. cirrhosa. The two plants are quite distinct, although some confusion has existed through the synonymous name of C. balearica being applied to both plants. C. calycina is a native of the Balearic Islands, and is recognised by its finely-divided evergreen leaves and greenish-white flowers a couple of inches or so across. Grown in an open position on rough stakes it attains a height of 12ft. or 15ft., and blossoms sparingly over a period of three months. Planted against a wall it often blossoms more freely, the wood probably becoming better ripened in such a position. Although a rare species, it is one of the oldest introduced plants of which we have any record, the period of its introduction being fixed over three centuries ago. Like other clematises, C. calycina thrives best in loamy soil which contains a good quantity of lime. W. D.

Kew.

CULTURE OF AMARYLLIS.

Judging from the improved specimens of amaryllis which year by year are to be seen at most of the important shows in this country, cultivators are devoting more time and space to this once neglected family of plants, and are setting aside a house or houses for its special culture. The amaryllis soon falls a victim to mealy bug, thrip, and red spider, if the conditions under which it is grown are poor. It does not require too rich a compost, neither does it thrive in too light a soil. After trying many experiments in the matter of composts, I find the best one to employ is composed of three parts loam to one part of leaf-mould, horse manure, charcoal, and sand, and it is all the better if this is mixed a month or so before potting.

The other essentials to the well-being of the amaryllis are (1) Judicious watering during and after flowering, and when the leaves are pushing. (2) Even temperature. (3) Careful potting.

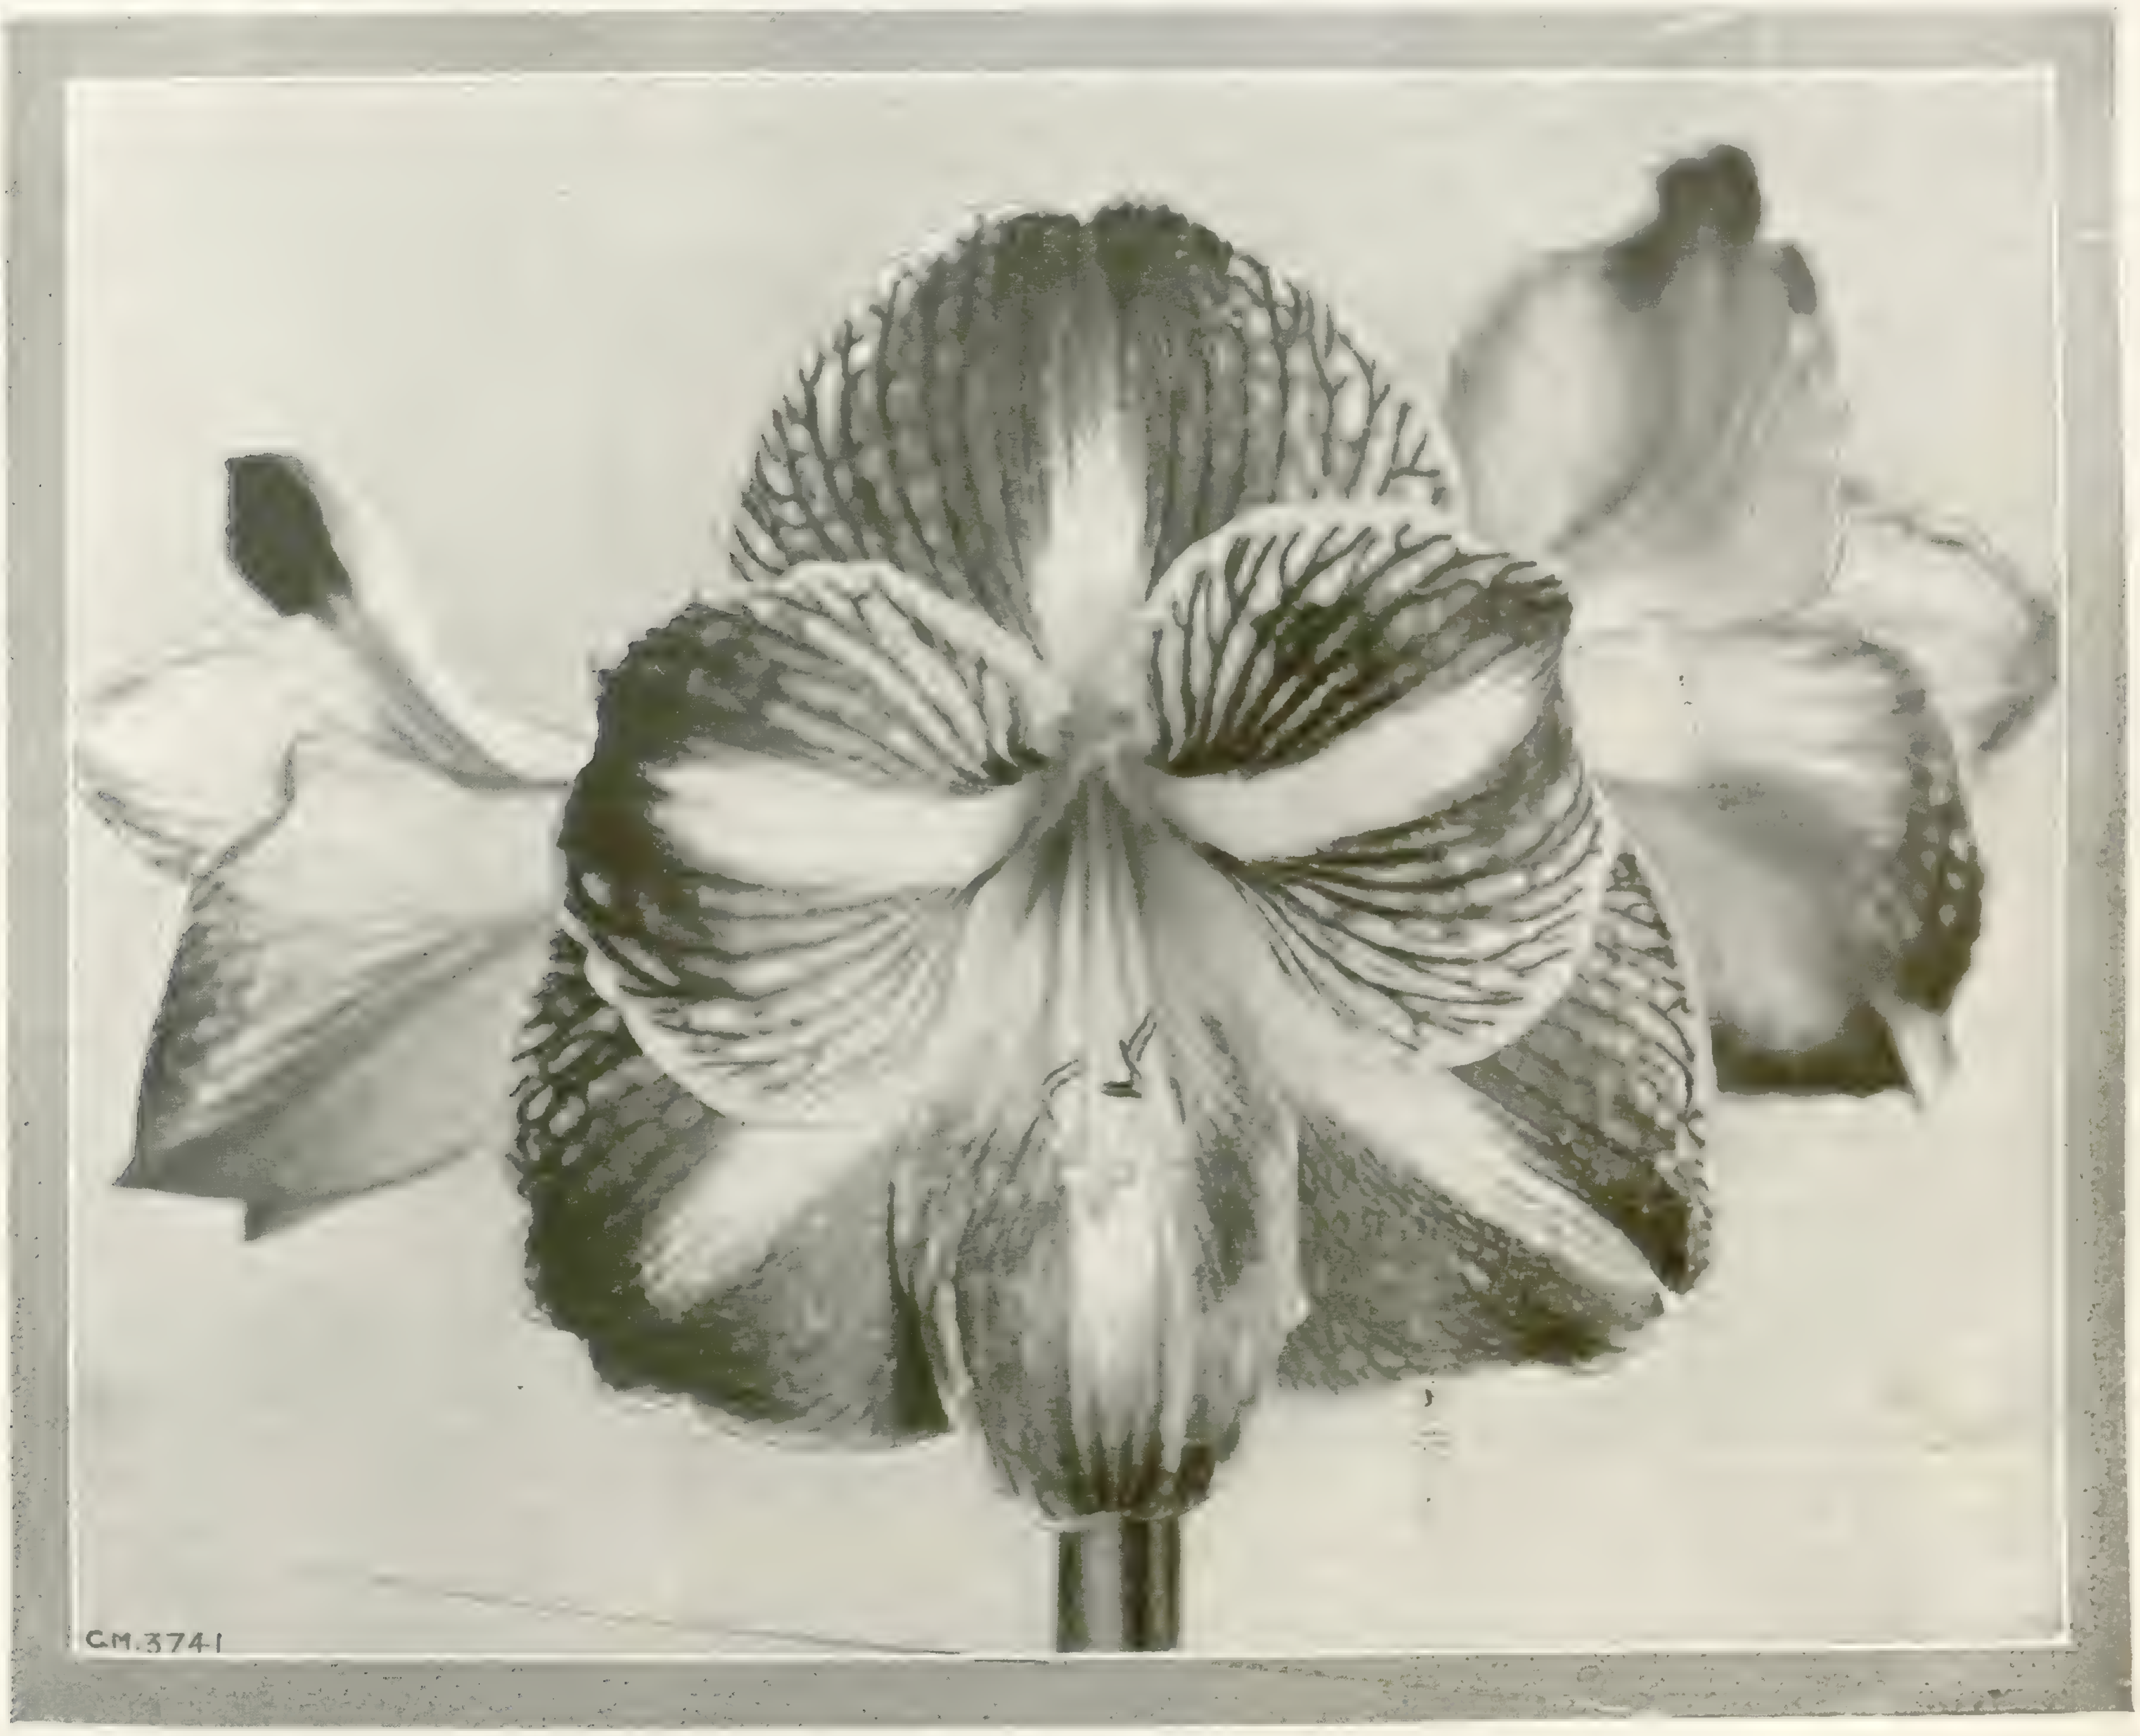
A frequent cause of failure is burying the bulbs too deeply. They should always be three parts out of the soil, and great care should be used to preserve the principal roots. It is not always necessary to repot flowering specimens annually, a little fresh soil, by way of top-dressing, made firm with the hand, is sometimes all that is needed.

Those who are commencing to raise seedlings I would impress with the necessity of thoroughly ripening the seeds, employing a light sandy compost, and just covering them. A brisk moist heat should cause the seeds to germinate in the course of two or three weeks, and in another seven weeks they will be fit to handle, and ready for their first potting. At this stage a temperature of 60 to 70 degrees is necessary to keep them steadily growing on to their flowering stage (a period of three years). A six-inch pot is quite large enough for the final potting, and smaller bulbs may be given a five-inch pot.

The flowering bulbs should be started in a fairly moist atmosphere, syringing only occasionally until signs of growth appear, when more liberal waterings may be given. It is not wise to leave the watering of these plants to the novice, particularly in the matter of the potted offsets, for at the time of removal these have not many roots, and they do not form fresh ones rapidly. It is best to have the pots plunged in a bed of oak leaves or tan, with a bottom heat of 75 degrees, and then they will want little moisture for the first few weeks after removal. During the resting period until the weather makes it impracticable, as much air and sun as possible should be let into the house, and water should be withheld if the pots are plunged, as the roots will derive sufficient moisture from this for quite six or seven weeks after watering ceases. It is not a good sign when the bulbs lose their leaves quickly.

A. Chapman.

Westonbirt Gardens.



AMARYLLIS LADY HOWICK.

A handsome crimson-scarlet and white variety, raised by Mr. A. Chapman, at Westonbirt.

THE BEST ANNUALS FOR THE FLOWER GARDEN.

When we have said all that we can say against annuals—their lateness in coming into flower, the damage they often sustain by bad weather, their short duration, and, not infrequently, their untidiness afterwards—the fact remains that they add so much to the beauty and interest of a garden that in these days we cannot afford to do without them; besides, there are many annuals in which the said drawbacks either do not exist, or, in which, by proper cultivation, these can be more or less completely overcome. The grounds at the Franco-British Exhibition must have been a veritable surprise to many as to the capabilities of this large class of plants, most of the floral display there being produced by plants raised from seed the same season.

A book recently appeared dealing almost entirely with hardy plants, and in this the writer had much to say about the rout of August—the interregnum of summer and autumn-flowering perennials. This is the season when annuals may be had at their best, and in the preparation of plans for beautifying our gardens we need to bear this fact in mind. The uses to which they may be put are various. For the present purpose I include under this heading any plant which may be sown and flowered in the same season. The purchase of seeds and the raising of stocks should be proceeded with at once.

Two annuals which need more care in the rearing than most are the verbena and the petunia, and they pay for it. It is essential to get bushy plants, whether they are to be pegged down or not, and in order to prevent any check to their growth it is worth while rearing them in small pots so that they may be planted out at the end of May with bloom almost in sight. I think few things make a more beautiful bed than either of these does when well-reared plants are put into good soil in a sunny position, the flowering time beginning in June and lasting till Michaelmas, or even later in a favourable season. Verbena seed can be obtained in mixed packets or in single colours, according to taste, the latter coming fairly true, while petunias can be obtained not only in varying colours but in different forms of flower, all of which are beautiful, and the scent not unpleasing on summer evenings.

One of the most commonly-grown annuals is the aster, which certainly makes a splendid display, though not for so long as we could wish. The numberless varieties range from six inches to two feet in height, and they can be used in different ways accordingly. They are late coming into flower, and need the best cultivation for success.

The ubiquitous stock, in its various forms and colours, must be given a place in every garden, as it is useful in beds, borders, and pots. It is on a chalky soil that it does best, and there it is worth growing largely, though plants grow untidy late in the summer. They need not be sown so early as some, for this reason.

One of the most beautiful bedding or border annuals is the salpiglossis, with its large alströmeria-like flowers, veined with the most delicate pencillings. Some of the colours are almost peculiar to this plant. It should be reared like the petunia, and is best not pegged down. It is, however, a most capricious plant in many places, dying off when in full bloom without apparent cause.

The portulaca rivals all plants in the brilliancy of its colouring, and where one has a light dry bed in a hot position no better place could be found for it. When rearing the plants it is worth potting them up, though they do not need to be sown so early as most, late March being soon enough.

One of the most paying of annuals for the border is the annual chrysanthemum, mainly C. coronarium and C. carinatum. They may be sown where they are to flower, as they are quite hardy, but are obtained earlier if sown under glass. They need to be given ample space if the flowering season is to be prolonged. Perhaps the most gorgeous of the annuals suitable for the mixed border is the African marigold. It is tender, and the earlier the plants are raised the better, as it lasts in any case until the frost comes. It pays for good feeding and plenty of space, and both this and the previous one may be used very effectively in concealing the later untidiness of perennials. The sweet scabious and the sweet sultan may be used to less effect in the same way, both being sown in the open as early in March as conditions permit. They are honey-scented flowers which everyone appreciates, and last in flower longer than most annuals, the yellow sweet sultan, however, being a smaller and more delicate plant than the white and the purple. On a very sunny border, where the soil is well cultivated, few things make a more brilliant display than the godetia, which should be sown where it is to flower as early in March as possible and given plenty of space, say eight inches each way. It is a plant for massing, but its season is not a very long one from the bedding point of view.

Our old favourite, the nasturtium, common as it is, must not be left out, as it is worthy of a place in any garden. The most gorgeous effects are produced when the dwarf varieties are grown in a rather poor and dry though well cultivated soil in full sunshine. In a rich soil the leaves hide much of the blossom. The climbing varieties, too, are very valuable, as we have few plants of such intensity of scarlet and crimson. They may be used as climbers or allowed to run about in the mixed border to cover up dying perennials, a few running over shrubs, too, producing a good effect. Some of the plants described as bedding annuals may be used in the mixed border, too, notably stocks and asters, and to these we might add the zinnia, which needs to be reared in the same way. Some of its colours are peculiar to itself, but it is of rather too leggy a habit to be used for the beds on the lawn. Some writer, I think the author of "A Gloucestershire Garden," has indeed said that a bed of double zinnias is the only thing which is as ugly as a bed of double tulips, but this can scarcely be regarded as a dispassionate utterance. Given a deep loamy soil and a warm position they last well into the autumn.

As to sweet peas, what can we say about them in a general article in this day of specialisation? Mention must be made of two other sweet-scented annuals which all should grow—mignonette and night-scented stock.

There are two or three hardy or half-hardy perennials which deserve a notice in any article upon annuals. Excellent perennials for treating as annuals are the Gaillardia grandiflora in its hybrid forms, the antirrhinum, and the pentstemon, which are good for both beds and borders. Seed sown in February, in heat, will produce fine flowering plants by early July, and these will last in flower until the frost comes, though the gaillardias fail in a wet autumn. The annual forms of the latter, too, are good. If a bed is made of antirrhinums it is recommended to confine it to those of one colour, when, given a sunny place in a soil not too rich the effect produced will be very fine. The gaillardias, too, cannot have too much sunshine, but like moisture and good feeding as well, as do the pentstemons also, but the latter, unlike almost any other plants treated as annuals, will do as well in partial shade as in sunshine. These three may be grown on in pots and planted out in the mixed border any time in June to fill blanks.

Mention has already been made of the nasturtium as a climber, as well as the sweet pea, and to these may be added, as a third, Eccremocarpus scaber, one of the most rapidly growing of all climbers, and beautiful alike in flower and foliage. If sown in February and treated as a tender bedding annual it will come into bloom late in June, or early in July, and last until the frost comes, growing ten or fifteen feet high in the meantime.

Everyone will notice omissions in the above list, and this must necessarily be the case in any selection of "the best." Many, however, of our favourites, by reason of their short period of effectiveness and their subsequent untidiness, are more suited to the reserve and cut-flower garden than the beds and borders of the more formal parts of the garden. As good annuals for cutting I might mention, in addition to some of the above, eschscholtzias, cornflowers, love-in-a-mist, larkspurs, Shirley and Iceland poppies, lupins, Cosmea bipinnata, Helianthus cucumerifolius, and coreopsis.

Alger Petts.

HOW TO GROW GARDENIAS SUCCESSFULLY.

These lovely fragrant flowering plants are greatly appreciated, and the beautiful wax-like blooms may be obtained in abundance from about Christmas time to the following May when the plants receive proper treatment. But very often they are unduly coddled, with the result that growers are disappointed. In order to grow gardenias successfully new shoots must be produced every year, duly matured, and buds formed.

Unless the houses in which the gardenias are planted can be practically given up to them I prefer to grow them in flower pots. In the latter case it is possible to move them from one structure to another, as occasion demands, and this is a very important matter. I know persons who can grow good plants, but are unable to procure specimens that will bloom. It is solely a matter of treatment.

After the flowers have faded the foliage should be thoroughly cleaned, all sediment and any insect pests being carefully removed. Mealy bug is the worst enemy, and it should be valiantly fought. Begin the season with clean foliage, and then it will not be a very difficult matter to keep it clean.

Gardenias may be pruned freely; all long, badly placed shoots should be cut back, but the young shoots on shorter branches must be left intact. Every plant that is potbound should be repotted as soon as possible in spring, the best compost being two parts of thinly-cut fibrous loam, one part of peat, and one of leaf-soil and well-rotted manure. Put in sufficient silver sand to make the whole mass porous. Remove the old crocks, carefully crock the new pots, and then pot firmly. When mixing the compost I first spread out the pulled turf and scatter the sand on it, turning the whole twice before adding the other ingredients. This causes the sand to adhere mostly to the turfy loam.

A stove temperature is necessary, and daily syringings with tepid water, and very careful watering and ventilation so long as the plants are growing. Shading is [illegible] advisable. During this period the plants are best grown in a low house, or a brick pit heated by hot-water pipes.

From July to September gardenias should be kept in a cold frame or pit. The new shoots will now have finished growth, and every effort should be made to have them thoroughly matured. I gradually harden the plants, so that they are [illegible] benefited by full exposure day and night except in stormy weather—the glass lights being removed during the warmest part of July and August. As the autumn approaches the flower buds become prominent, and such plants may be forced later on; in this way splendid specimens are produced, with hard wood, and thick, leathery, healthy green leaves.

During the first half of September the glass lights should be put on, and the plants taken to their winter quarters by the end of the month. While they are in the cold frames very careful watering should be the rule, and when you are sure that the pots are well filled with roots, give weak doses of liquid manure, [illegible] after the plants are removed to the warm house. Forcing may commence in November.

Cuttings root readily in a sandy soil under a hand-glass, especially if a little bottom heat can be given.

Geo. Garner.

HERBACEOUS PÆONIES.

Herbaceous pæonies are among the noblest hardy plants in the garden during early summer. They are unsurpassed for variety and for the delicate colours of the flowers, which in many instances are richly perfumed, while the plants are robust and free-flowering to a high degree. An awful poverty marks a garden where the pæony is not represented, while a rich beauty characterises the garden where pæonies are lavishly planted. Pæonies are neither expensive to procure or to maintain. The flowers enter into friendly rivalry with the rose, in texture of petal, delicacy of colour and fragrance, but, fortunately, they offer no invidious comparisons, as each is distinct in character and both have their season and special mission, so that no contradiction of interests can ever force them to be placed in the balance to the discredit of either. The colours range from purest white to full rich crimson.

To command success with herbaceous pæonies is neither difficult nor expensive, yet the necessary conditions should be provided in a thorough manner. The plants have a wonderful hold upon life, for the smallest bud will grow; on the other hand they are very impatient of removal, so that planting should always be regarded as permanent. They luxuriate in deep, rich, loamy soil, and in positions well drained; soil two feet in depth will support good specimens, but quite thirty inches should be secured, and if the depth is in excess of this so much the better. The ground should be well trenched, and have a liberal dressing of rich manure worked into it; on that of a retentive nature drainage must be provided and the staple mixed with wood ashes or soil that has been charred. Where groups are formed among other subjects and the soil is of poor quality, the bulk should be removed, and a compost of richer material added.

This work should be carried out early in autumn, allowing the ground to settle for a fortnight, when it will be in excellent condition for planting. Choose a day when the soil works freely, mark out the positions and plant the crowns about two inches below the soil level, carefully working soil among the fleshy roots and making all firm as planting proceeds. Amateurs frequently err in employing too large clumps, and with home-grown crowns this temptation is naturally great. These specimens should in every case be divided, as six to eight strong growths form a good plant. The distance apart in planting should never be less than four feet when in lines, and eighteen inches apart in groups of three among other hardy plants. Magnificent effects are produced by intergrouping pæonies with narcissus, liliums, and a few of the best and lightest Michaelmas daisies, and this arrangement gives a continuous display throughout the year and requires the minimum of trouble.

Failing planting in autumn, the earliest opportunity should be embraced in spring, but from late planting no display need be looked for the first season. There are endless positions available for planting pæonies in, but they are most effective in great masses in beds or borders, and as they bear a considerable amount of shade their utility is so much the greater. Many of the species and older varieties are beautiful when planted in grass, or in open clearings in woods, but they should never be planted near the roots of forest trees or vigorous shrubs. Aspects should be selected where the plants will follow in succession; a gentle slope or wall-foot open to the sun will favour early flowering, while positions partly shaded will naturally prolong the season.

Subsequent treatment consists in applying a yearly dressing of rich manure around the crowns after the foliage is removed in autumn, followed by a light dusting of some approved fertiliser lightly forked into the soil previous to growth commencing in spring. Mulching with short litter is advantageous in dry summers, and copious supplies of liquid manure will readily stimulate a vigorous growth.

The present race of garden pæonies has really originated from two species, namely P. officinalis, an European plant, and P. albiflora, a native of Siberia, and both these have been known in England for over 300 years. It is chiefly in gardens where rare plants are specialised, in botanical gardens, and in a few nurseries that we find any considerable number of pæony species cultivated, and to the great body of cultivators the pæony is a garden flower inseparably associated with the names of great raisers like Kelway of Langport, Lemoine of Nancy, etc. The greatest interest among species is centered at present in those having deep yellow flowers, of which P. Delavayi is the latest and most valuable addition, and we are not without hope that this species may hybridise and yield a race of true yellow pæonies as vigorous as the older forms.

Varieties of pæonies are beyond number, and they range in price from ninepence to half-a-guinea or more. Fortunately the price is no indication of quality, as in these high-priced varieties it primarily implies that the stock is as yet limited. We have in the variety illustrated one which is representative of a group, moderate in price, yet beautiful to a degree. Mdme. Calot is a typical garden pæony, very double and of good form; the colour is flesh-white, tinted rose on the guard petals, giving it the appearance of blush pink. To complete a dozen of the most distinct and inexpensive varieties I would include Alexander Dumas, rose and cream; Carnea elegans, rose-yellow and rose; Festiva maxima, white, flaked red; Formosa alba, white and cream; Humei, white; lutea plenissima, self primrose; Mdme. Celie, crimson; Magnifica, pink and blush white; Ne Plus Ultra, peach and white; Reine des Françaises, rose and white; and Vanguard, cherry-rose.

Equally distinct and beautiful are the single herbaceous pæonies, the broad, shell-like petals enclosing a great boss of golden stamens, so that the flowers appear like glorified single roses. A superb dozen, all distinct, includes Argus, bright rose;

HERBACEOUS PÆONY MADAME CALOT.
A charming flesh-pink variety with rosy guard petals; finely exhibited by Messrs. G. Bunyard and Co., last summer.

Autumnus, purple; Emily, bright pink; Nellie, blush white; Snowflake, white; Stanley, maroon; The Queen, white and blush; The Lady, rosy lilac; Viscount Cross, cherry rose; decora alba, white; officinalis splendens, crimson; and Wittmanniana, pale yellow.

Walmsgate Gardens. THOMAS SMITH.

DWARF OR FRENCH BEANS.

It is exactly four hundred years since the introduction into this country of the dwarf type of bean, and, as was the case with many other of our favourite vegetables, no very striking improvement seems to have been made until within the last fifty years or so: at least it is safe to say that the best and most popular varieties of the present day have been raised during this last period. For supplying early crops of kidney beans, as well as very late ones, the French bean is invaluable; and, in addition to this, when the pods are picked at the right moment, before there is any suspicion of becoming old and stringy, the quality is certainly much more refined than that of the ordinary scarlet runner bean.

Fortunately, this vegetable is not at all fastidious as to soil; nevertheless, it is important that in all cases the ground should be deeply tilled and well enriched with manure, and the earlier this can be accomplished during the winter months the better, and especially does this apply to heavy soils. Immediately this work is performed, apply a thoroughly good dressing of either soot or wood ashes, and when the soil is destitute of lime apply a fair dressing of this also. Except for producing crops during August and September, the site for preference should be a sheltered one, facing south or south-west.

The French bean is among the most tender of our kitchen garden crops, consequently seeds must not be sown too early in the open. But to ensure very early crops a capital plan is that of sowing early in April, either in pots or boxes, in a cool house or cold frame. The plants should be kept very cool, and not allowed to become drawn; place them at the foot of a south wall or building, where they can easily be protected if necessary, and thoroughly harden off before planting out, and even after this it may be advisable to slightly protect them against late frosts and cold, cutting winds. Small spruce boughs placed on either side of the row make a splendid protection.

Towards the end of April, after pointing over the land, which has been previously trenched or dug, seeds may be sown in the open. Sow the seeds thinly in double lines, about two inches deep, and allow about three feet between the rows. Small sowings should be made at intervals of about a fortnight until the end of July. The chief fault in the successful culture of this vegetable is overcrowding; generally speaking, three or four plants occupy the space which should be alloted to one, and particularly does this apply to the stronger growing varieties, such as Canadian Wonder, Magnum Bonum, and Ne Plus Ultra. The latest sowings will in many districts need protection against early frosts, and where old lights can be brought into use for this purpose it frequently happens that the crop will continue to bear for fully a month or six weeks after the tall growing beans are killed by frost.

During spells of drought it is most essential that the plants be kept well supplied with moisture, both in the form of clear water and liquid manure. Drainings from the farmyard, properly diluted, will suit them admirably. Mulching with long litter from the stableyard on all kinds of land during hot weather is extremely beneficial, and does much to improve the quality of the crops, as well as extend the duration of productiveness.

Fortunately, the dwarf bean has few enemies, and these can be overcome easily. Where slugs abound, and in some seasons these probably give more trouble than anything else, by using liberal supplies of finely-sifted cinder ashes, they can generally be kept at bay. Black aphis and red spider sometimes attack them, but frequent dampings overhead with clear water, and keeping the roots well supplied with moisture, will act as preventives against the latter, and strong soft soap and water is a certain remedy for aphis of all sorts.

Veitch's Progress is a distinct and very quickly maturing variety, well suited for very early supplies. Ne Plus Ultra, Magnum Bonum, and Canadian Wonder are each splendid varieties, the latter being the finest for exhibition purposes.

Aldenham Gardens. E. BECKETT.

CONSERVATORY PLANTS FROM SEEDS.

It is to plants raised from seeds that we look for many of our brightest displays in the conservatory, and as the various batches can be brought on in relays they do not overcrowd the houses and the frames in which they make their growth. Plants that are only flowered once, whether of an annual or a perennial character, are less troublesome to deal with at certain times of the year than are those which have to be kept over from year to year. With a little good management as to time of sowing, etc., surprisingly good results can be had from a very limited amount of glass when plants from seeds are mainly depended on, for the time of sowing and growing varies almost as much as the character of the plants themselves, and from the earliest months of the year up to, say, the end of September, there are always young plants of some kind or other which are in the stages when they require little room, and which can be kept in that condition until some of the rest have done their work and been cleared out.

The spring is, of course, the season when the larger number of these plants are sown, beginning quite early in the year with tuberous begonias, gloxinias, torenias, and continuing with cinerarias, of which batches may be sown from March to May; Lobelia tenuior, a very useful plant for conservatory decoration; Campanula pyramidalis, balsams, and celosias, Chinese and other primulas, such as P. floribunda, P. verticillata, and P. Kewensis. Then in the summer the herbaceous calceolarias must be taken in hand, to be followed soon by cyclamen, streptocarpuses, and those most useful conservatory plants, the schizanthuses. The pretty little Saintpaulia ionantha, too, must not be forgotten, for, though these, like some of the foregoing, may be raised in other ways, they make the better plants when grown from seeds.

When growing plants from seeds, perhaps the most important thing to bear in mind is that, from the start until they have reached their flowering stage, they should never be subjected to anything in the nature of a check. The roots must be always active if good results are to be obtained. Checks may be given in many ways. The seedlings may be either over or under watered, or they may be raised or potted on in unsuitable soil, and either of these things will check or hold back the necessary root action; but perhaps the most common cause of such checks is that the young plants are allowed to become rootbound, either by growing them too closely together or by leaving them too long in the pots between the necessary shifts that have to be given before they reach the size of pot in which they are to flower. Very few seedling plants will take freely to new soil when once the roots have been allowed to coil themselves up into a matted mass, and though it is often difficult to find time to do the necessary potting, yet when the right time comes, it is only by doing the work that we can command good results.

Personally, I think that "boxing off" rather than potting off seedlings from the seed pans is conducive to a good start, and that this should be done early, for no matter what care is expended in the preparation of soil for seedlings, such soil has a tendency to become sour quickly, owing to the paucity of roots that are made in the early stages of a seedling, consequently the earlier they can be moved out of this soil the better. On the other hand, they start away more quickly when transplanted in colonies in other boxes than they do if potted off singly, for plants in small pots have to be too frequently watered, the small quantity of soil contained in each pot becoming quickly dry. Boxing off obviates this, but in almost all cases only shallow boxes, containing a very little depth of soil should be used.

Another thing to make note of is that only seeds of a good "strain" of plant should be used. One often sees batches of what can only be described as rubbish when contrasted with similar plants of a better strain; and when it is remembered that only the same skill is required on the part of the grower to produce these batches, it should be easy to understand the false economy of buying cheap or badly selected seeds. Our best seedsmen take great pains with their stocks, and the care given should be encouraged by the grower only selecting the best. One should also consider in this connection what particular strain is "the best" for one's individual purpose. The strain of cinerarias, for instance, which would please the man with the eye and heart of an old florist, who cares principally for the shape and size of the individual flower, would not please the grower for cut flowers or for the background of conservatory groups, as for these latter purposes the newer stellate forms, with their tall habit of growth, would be most suitable, and the same thing follows with most plants.

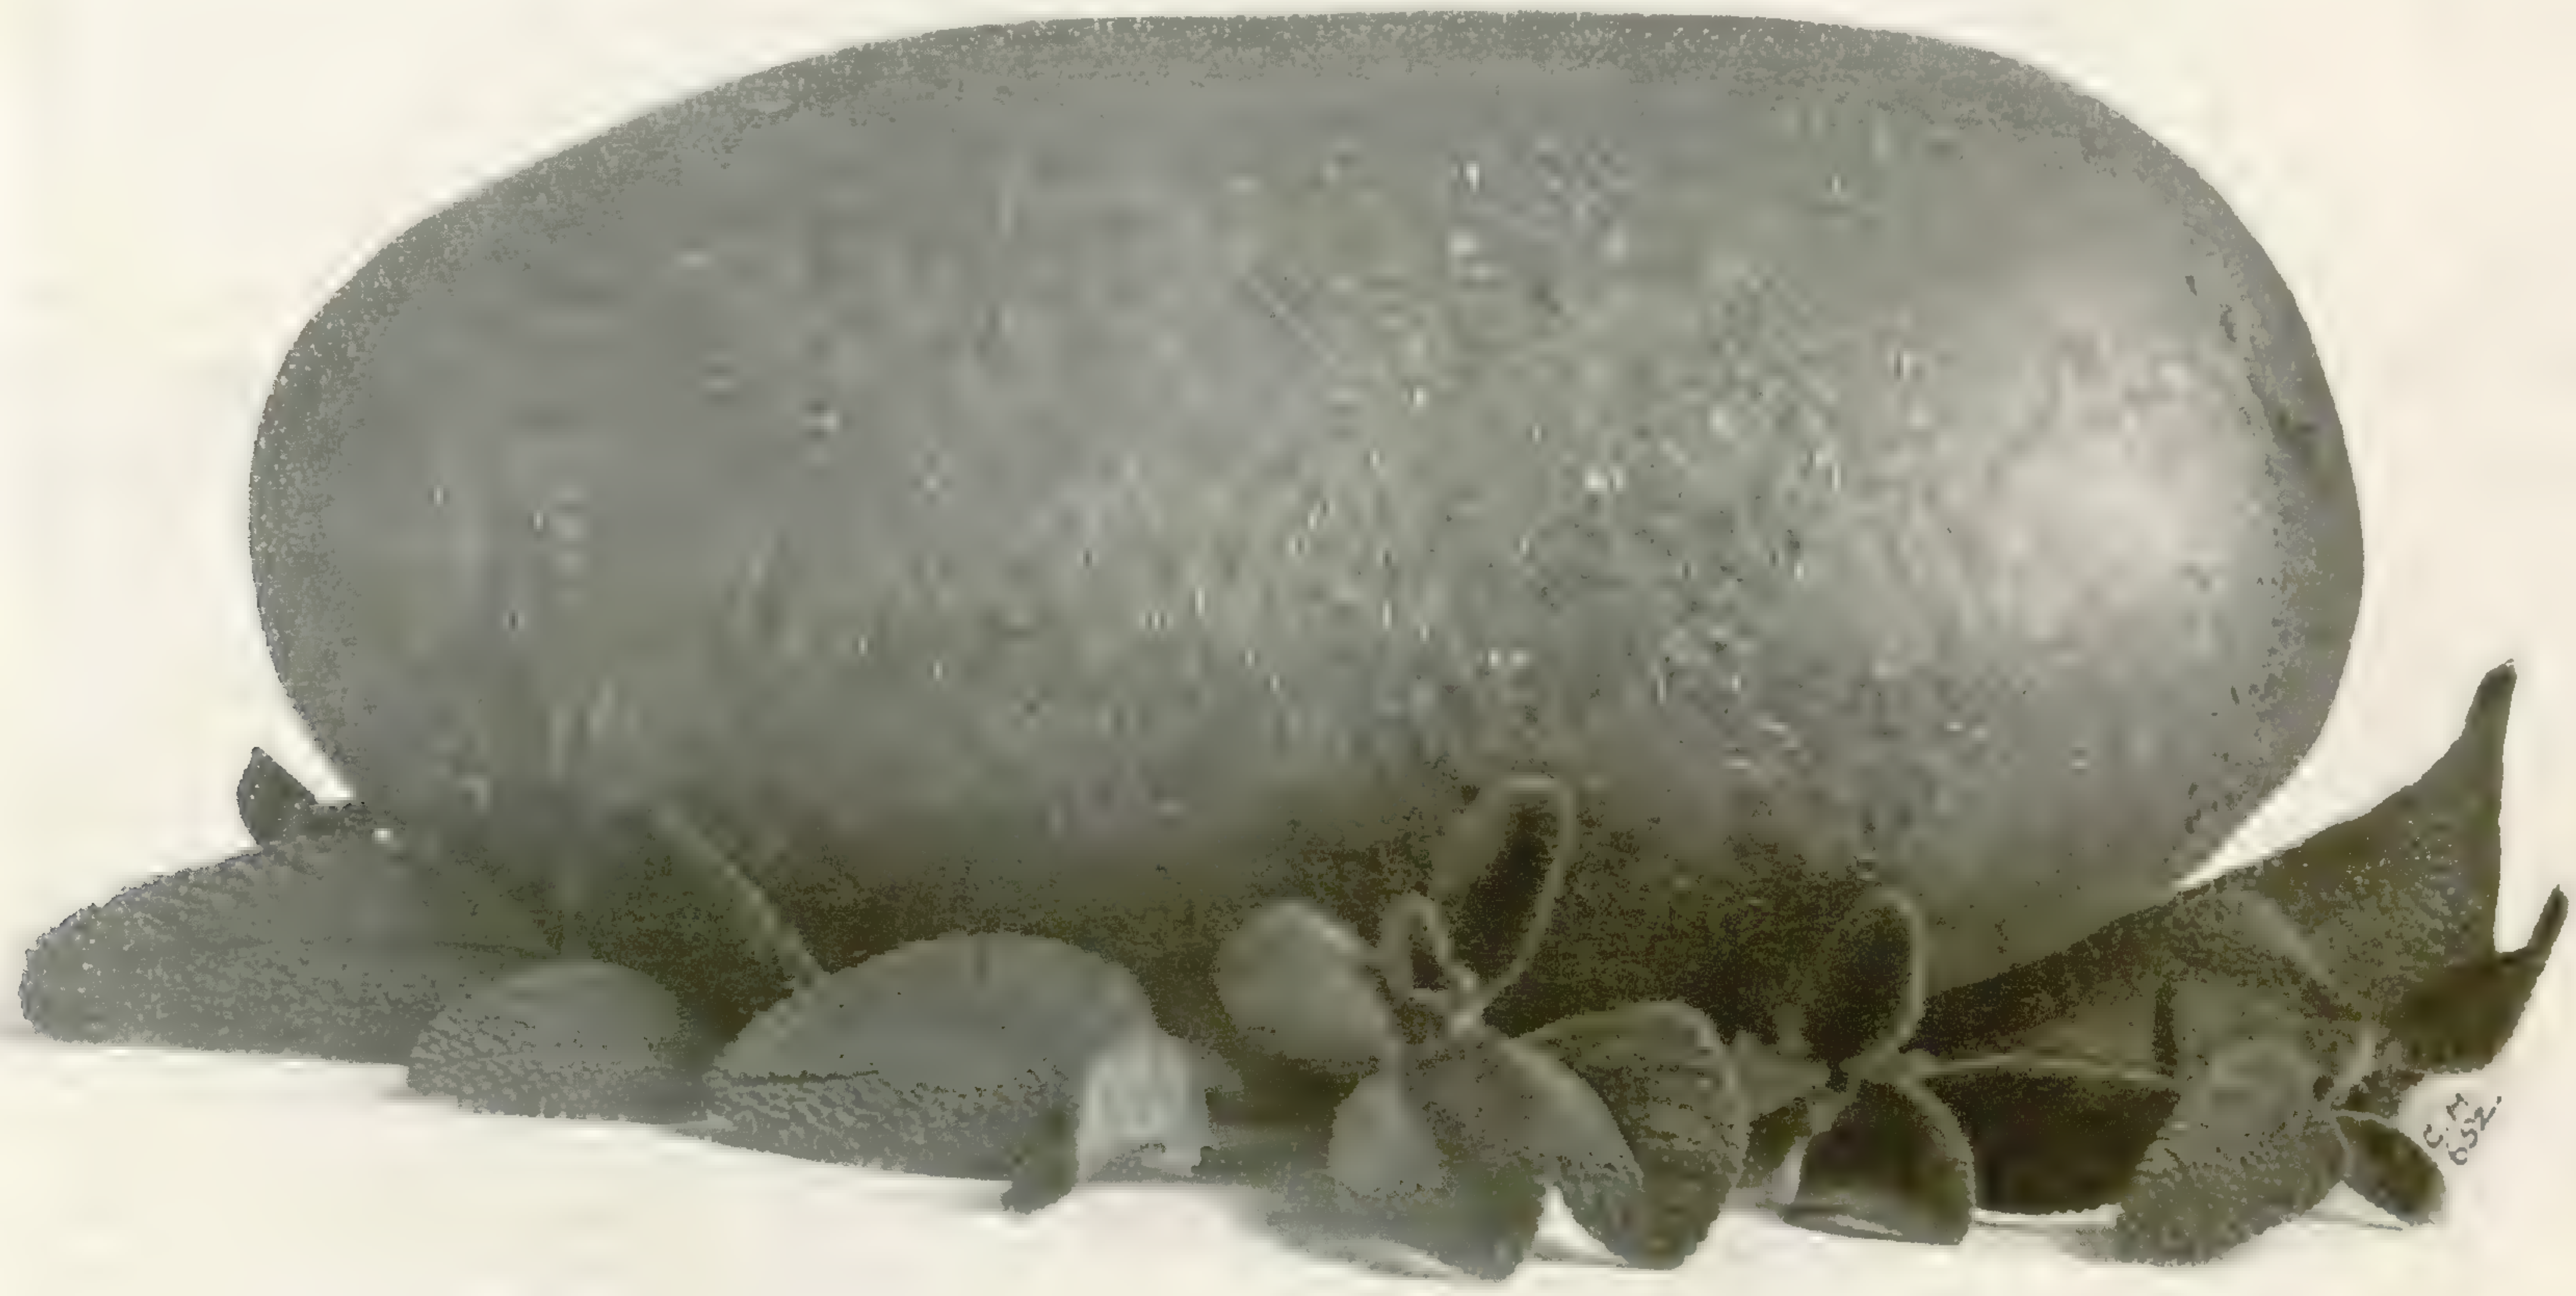
Again, for conservatory decoration the choice of the proper colours should be a main consideration, and here one may say that large batches of a given colour are far more effective than mixtures of various shades and colours. J. C. TALLACK.

Shipley Hall Gardens.

Tunica saxifraga rosea fl.-pl.—In many respects Tunica saxifraga resembles a miniature form of dianthus, with which it shares affinity from its position in the same natural order. This old-established rock plant has sprung into sudden notoriety by reason of its distinguished double-flowered offspring. Tunica saxifraga fl.-pl. is a charming double pink flower, in some ways it resembles a gypsophila, and, provided it maintains the vigour of the type when grown under the same trying conditions in the open it will certainly meet with a most [illegible] welcome from lovers of these dwarf [illegible] subjects. That it is a distinct gain to its class is borne out by the Award of Merit bestowed upon it at the Holland House Show last summer. I believe the variety originated as a sport from the type, on the Continent, about two years ago.—THOMAS S[illegible]

NEWER POTATOES.

In making active preparations for the planting season which will soon be with us, the question arises in one's mind, What does the future hold to startle us with among potatoes? We have, indeed, settled down upon quieter times since the boom of only a few years back, and perhaps it is as well that so quiet a time should follow upon such an upheaval. We sometimes think that, constitutionally, the potato is not so easily spoiled as one might at times imagine. There are, of course, enemies enough, both in our own country and in others, and what with the ordinary potato diseases, scab, black scab, and cultural defects, we do sometimes wonder from whence comes all the fine, clean stocks that are so plentifully and cheaply placed upon the market. One may, however, safely say that there are fewer worn-out stocks in England at the present time than for very many years back. The seed trade knows, and has known for years, what climatic and cultural conditions are best suited to either maintain vigour or reinvigorate any degeneracy in a good type.



KIDNEY POTATO WHITE CITY.
A free cropping new variety, raised by Messrs. Sutton and Sons.

The tendency of late years to grow fewer varieties has also made headway, which is a very desirable thing. Looking into old notebooks of some twenty-six years or more ago, I find we do not now possess so many distinctive potatoes as were then grown; and what a business it was to be sure trying to keep each variety true. Scores of them were useless as human food, and the same may be said of many of the varieties of to-day, more especially some of the coloured ones. I do not complain of the quality of some of our maincrop potatoes of to-day, because, generally speaking, the quality is good, providing the cooking is good also. We have The Factor type, which commenced with Triumph or Up-to-Date, and so good has this type proved to be that it has more synonyms than any other ever placed upon the English market.

During late years we have made rapid strides in the annual seeding of plants that are not really annuals, and this rapid multiplication has resulted in changes and unlooked-for colours in a remarkably short period. I wonder, will it become possible as time goes by, to bring down to a reasonable stage of purity a good type of potato that will yield a serviceable crop of tubers from seed the same year as sown? Perhaps we should more nearly approach the disease-proof stage if that could be done. Seedling potatoes, under the usual conditions, give endless trouble and expense, because so very few ever reach any market value, and, so long as the present system of raising goes on, so long will the extraordinary diversity in form, colour, cropping, and varying stages of strength show in the progeny. The process of working down a good type to a pure stage before recommencing to work upon them would take time, but there would be something more definite to work upon. New life seems to be necessary in potatoes from time to time, and when under the vegetative method of annual reproduction their constitution is impaired beyond a paying stage, it relieves us to know that there are good firms sparing neither trouble nor expense in trying to maintain the present useful standard, and even improve upon it.

New varieties, to meet present day requirements, must possess several qualities. They must be free growers, free croppers, shallow-eyed, of good quality, and good disease resisters, and, preferably, have white skins. It is no mean achievement to secure all these qualities in combination, so that we do not wonder so much at only a very few genuinely distinct varieties appearing. When visiting the White City, towards its closing days, we saw many things that are not likely to fade from our memory, and not the least of these was a new potato given by the raisers, Messrs. Sutton and Sons, the name of White City, which was to be seen in quantity and fine form. Having grown the variety and also seen it growing with others, I have not the least hesitation in saying that it is a distinct break from any other variety now in commerce, and that it possesses all the good qualities that one naturally looks for in a paying maincrop potato. The tubers are longer than round, not too thick, very shallow-eyed, and freely produced, with a distinctive haulm that stands up well, but is succulent enough for the rapid transmission of sap. Everyone should give this (and I predict it will become a standard sort) a trial. Another extraordinary cropping potato is Long Keeper; on light, well-manured land, one is led to wonder how so many tubers could be crowded in the soil; this would make a fine potato for baking purposes. President, or President Kruger (and other names) is a German variety, very heavy cropping, and though too ugly for a refined table, it has its admirers in a few districts. Sir John Llewelyn has had many admirers, and now Lady Llewelyn appears to be making headway in Scotland; my old friend, Mr. James Harris, is responsible for this good second early sort, which in many respects resembles Sir John Llewelyn. The Colleen, although not quite new, is an extraordinary cropping variety, that is not so largely grown as it should be.

Eclipse and Early Favourite ought to be tried as early varieties. The former is thought a good deal of in Northern districts and is very shapely, in some cases nearly round and others more pebble-shaped; a fine cropping variety and of very good quality. Sutton's Gladiator is an early potato that did well in some districts, but until last summer it never in anyway satisfied me as a remunerative cropper. When giving it another trial I was assured that the stock was a vigorous one, and such it proved to be, and I never experienced greater satisfaction with any early variety. The tubers were of excellent all-round quality, superior to Ringleader in crop, and of better quality than May Queen. Of the excellent Duke of York type I saw some fine crops lifted of Midlothian Early, and there is do doubt about it, this potato is the one that the poor man must have; an immense cropper, handsome in appearance, and of very passable table quality; what more is wanted? Dobbie's Favourite is a good second early variety that would be difficult to beat as regards quality, and when we speak of quality we never forget that Windsor Castle has never been surpassed amongst the second early section. Sutton's Red Kidney is another new potato I have grown; its crop and appearance pleased me very much, but upon my light soil the tubers did not reach the size usually wished for. Upon richer and moister soils the tubers are very fine and perfect models of refinement.

Reading. C. Foster.

FRENCH GARDENING IN ENGLAND.

Shall we, in the days that are to come, look out over landscapes dotted with enclosures surrounded by corrugated iron fences, and covered with frames, cloches, handlights, and the rest of the paraphernalia connected with the equipment of a French garden? Will it be a familiar sight in the future to see men (and women) not moving manure about in the old-time barrow, but carrying it on their backs in true Parisian style? Time will tell, but if such a thing does happen, and people come back to the land through the doors of French gardens (mind you, I do not say they will), the credit of starting the movement, and booming it for all, perhaps more than it is worth, will not belong to steadygoing horticultural journals, but to an enterprising daily Press, that also sets out to run a small farm, and undertakes to show the British public how the landless man from the town can be put on the manless land in the country and make it pay.

It is no good saying you are not interested in French gardening, because you cannot help yourself; the daily Press will not let you, and when that much-talked-about individual, the man in the street, reads in his morning paper, over his breakfast table, glowing accounts about golden soil and the money there is to be made out of an acre of land devoted to French gardening, he compares it with the modest salary he toils hard for, sighs that he was not brought up to a horticultural career, and wonders whether, with the aid of a little handbook on the subject, he could invest his little all in frames and cloches and go straight to fortune. With implicit confidence in his newspaper and the golden soil journalists, he asks himself what are the market gardeners doing that they do not give up their old-world methods and take this short cut to independence and riches, instead of slaving week in week out for a mere living? Perhaps he sets down the reason to want of enterprise, characteristic British conservatism, or something else, but in his simplicity he fails to understand it, and chides his brother of the soil for not jumping at the golden opportunity that is placed before him.

It is no good for men engaged in horticulture to excuse themselves from French gardening on the grounds that they do not understand it, because it is all so simple and easy, and a shilling spent on a handbook brings the knowledge in front of one's very nose, with full particulars of expenditure, returns that may be expected, and estimated profits. After reading one of these encouraging little volumes the question naturally suggests itself, why has it been left to the journalists of the twentieth century to discover French gardening? How is it that our market gardeners and commercial horticulturists have gone on all these years trying to compete in the market with the French gardener, and missing all these splendid chances without thinking of copying the methods of the above? The answer does not come so easily as the question, and the reader had better be left to form his own conclusions. But those who have faith in the possibilities of French gardening need not hesitate if there is no difficulty about capital, for the handbook tells how it is done, cloches, frames, and mats are getting to be quite a commodity, and seedsmen advertise and supply seeds suitable for the purpose on the most favourable terms. Why then should anyone pause when such a chance of fortune—£700 an acre—is held out before them?

And, just fancy! Some sceptical-minded people have pictured the old country with French gardens dotted about it, and they have ventured to suggest that if the French system became general the supply of salads and the rest might exceed the demand, prices would come down, and profits be diminished. One has heard this argument put forward, but the boomer of French gardening has got the answer ready in the contention that the supply will create the demand. He illustrates tomatoes, and talks of the day when nobody would eat one, and shows how the taste became acquired and there arose a national demand for the love-apple when the supply was forthcoming. Nor is this all, for he rushes into figures, and tells you the quantity of salading, out-of-season carrots, early turnips, etc., that are eaten in France compared to England, and pictures the difference there would be if French gardens were general. Oh, ye of little faith, the French garden advocate seems to say, why do ye waver, don't you see how easy it all is, how you can create the demand by providing the supply, and educate John Bull up to being as fond of lettuces and radishes out of their natural season as his cousin over the English Channel; and don't you see how you can teach him to eat these things, as you have taught him to eat tomatoes? As a matter of logic, it all seems simple, but there are some who form a different estimate of John Bull's appetite, and have their doubts about making him as big a salad eater as his friend Monsieur Jacques over the water.

It is doubtless encouraging to the promoters of the French gardening boom to know that, to a certain extent, it has caught on. A number of French gardens have been started, and are probably doing well, while preparations are in hand for the establishment of others. Speaking quite seriously, there appears to be no reason why a number of French gardens in suitable places should not do very well, but the fear is too many of them, because, after all, John Bull is not an easy fellow to move where his habits of eating are concerned, and such a thing as over-supply of forced produce is possible, though one may be put down as being a little bit old-fashioned for thinking so.

But wait, ye British-French gardeners, you have another string to your bow, if you only realise it. Listen, while I whisper—take paying pupils in. There, keep it to yourself, but quite recently I saw a glowing advertisement in a leading and influential morning paper, which stated that for the payment of a quite handsome premium, French gardening could be learnt in a properly equipped establishment, and, what is more, there were inducements offered in the way of sport and congenial society. I wonder which would be likely to pay best, the cloches or the pupils; but that is part of another story, and no particulars were given as to whether the pupils would be expected to shoulder the manure baskets. Still one knows that in farming and other occupations premium paying pupils are profitable crops, and the same thing may apply to French gardening.

By the way, French gardening is catching on in the education world, and I read the other day of one Education Committee voting a certain sum of money for carrying out experiments with frames and cloches, while, I am told that the inspectors who supervise industrial and reformatory schools are quite keen about French gardening being part of the curriculum of manual instruction. You see then that even in this class there is a prospect of raising a race of British-French gardeners. I have not as yet heard of French gardens being established in connection with elementary schools, but if the idea should get fixed at the Board of Education offices there is no telling what might happen, and if the long-suffering ratepayer has to contribute to the provision of frames and cloches to grow lettuces and radishes in the school playground.

I spoke at the beginning of the possibility of the landscape being dotted over with French gardens—we shall perhaps view them then from aeroplanes, but if such a thing does come about, I hope some new method of fencing will come into fashion. I urge this because I have seen one French garden which is surrounded by a wall of corrugated iron seven or eight feet high, and never have I beheld anything more unsightly. Indeed, garden it could not be called, and a more correct term would be frame-yard enclosed in a tin case. Perhaps all French gardens are not like this one, and I hope not, particularly if they are to become general; and if it is necessary to provide something for protection, and block out the vision of an inquisitive public, let us pray that something less ugly than corrugated iron fences can be found for the purpose.

A BRITISH GARDENER.

PREVENTIVE MEASURES AND INSECT PESTS.

To destroy insect pests we have remedies in plenty, that are more or less effective, and there are people who will go to the expense of purchasing these things and spend time in applying them who deliberately ignore the simple precaution that may be taken to avoid the risks of attack in the future. Let me put a case, for the statement should be of value at the present season. I am acquainted with a district where the soil is light and [illegible] and the great scourge is the onion maggot.

Last June I visited quite fifty gardens and allotments in the district referred to. The onion beds everywhere looked healthy and promising. I visited them again in August and for the most part the beds were [illegible] wrecks, but what did I behold? The brown withered tops which were evidence of the trouble, but in very few cases had the maggot-infested plants been removed from the ground. In other words, the pests had been allowed to increase tenfold or more just because the people will not go to the trouble to promptly pull up the maggot-ridden plants and burn them. If the onion beds in this district fall a prey to maggot the coming season, as in all probability they will, who is most to blame? Why the growers themselves. It is true that a few take the necessary precaution of removing the affected plants, but their efforts can have little effect while their neighbours round about are breeding the onion fly.

I contend that in this district, if all the persons who grow onions, and most of the people attempt it, would join hands and undertake to burn every maggot-infested plant as soon as it was observed, they would do more to reduce the evil than is possible by the use of insecticides and other remedies. The same thing applies to other pests besides onion maggot, and the general fault is that when a crop fails through some insect attack it is [illegible] left to its fate, and the pests are allowed to increase their kind, with the natural result that the damage is greater the following season.

H.

THE JOHN INNES HORTICULTURAL INSTITUTION.

As briefly announced in a recent issue the late Mr. John Innes, who was a resident of Merton, Surrey, and died in 1904, left a large sum of money for charitable, educational, and other objects, chief among them being an institution in which the practice and science of gardening would be taught, and the investigations of matters associated with horticulture would be carried on. A scheme for the administration of the bequest has been prepared by the Charity Commissioners, and published within the past few weeks. Provision has been made in the scheme for the payment by the trustees of yearly sums out of the income derived from the investments for the maintenance of a park and a boys' club at Merton, for the provision of scholarships tenable at a local school, and certain charitable objects. These sums and certain annuities left by the late Mr. Innes, will amount in the aggregate to an annual sum of about £4,400. The residue of the estate, which is estimated to produce about £5,000 per annum, will be applied to the foundation and maintenance of an institution to be known as the John Innes Horticultural Institution, whose object shall be the promotion of horticultural instruction, experiment, and research. The house formerly known as the Manor Farm, Merton, and a portion, not exceeding two acres, of the grounds, are to be devoted to the purposes of the institution. The trustees are empowered to select the two acres from such portion of the grounds as they may consider the most suitable, and subject to the consent of the Charity Commissioners, they may provide additional land, of which a sufficient area in the neighbourhood is available.

The management of the institution will be entrusted to a council consisting of three trustees, who will be ex-officio members, and nine representative members. Two of the latter will be appointed by the Board of Agriculture, and one each by the following bodies: The Royal Horticultural Society, the Fruiterers' Company, the National Fruit-growers' Federation, the Hebdomadal Council of the University of Oxford, the Council of the Senate of the University of Cambridge, the Senate of the University of London, and the Governing Body of the Imperial College of Science and Technology.

The functions of the Council are defined in the scheme for the administration of the institution, as follows:

(a) To establish and maintain the institution for the purposes of affording practical and scientific training for those engaged, or desiring to be engaged, in the industry or employment of horticulture.

(b) To carry out investigations and research, whether of a practical or scientific nature, into any matters having reference to the growth of trees and plants generally, but especially of fruit trees, shrubs, fruit, vegetables, and flowers, and to investigate and demonstrate the best methods of their cultivation, their habits and leading characteristics, together with the soils and localities in which they may be most inclined to flourish.

(c) To endeavour to improve existing varieties, or to create and introduce new ones.

(d) To impart information, whether of a practical or scientific character, on all matters connected with the above, and generally to endeavour to promote as far as may be in every way the interests of all connected with, or desiring to be connected with, the industry or employment of horticulture.

(e) Generally to pursue any course incidental or conducive to the attainment of the objects referred to in paragraphs (a), (b), (c), and (d) of this clause.

No such munificent bequest has, in the history of gardening in this country, been made for the promotion of horticultural instruction, experiment, and research, and, as the opportunities of the institution for good work will be great, we trust the desire of the testator may be fully realised.

SEASONABLE NOTES ON SWEET PEAS.

The most seasonable advice I can give to those who wish to grow the Spencer type of sweet pea novelties or varieties is to have extra packets of seed ready to hand to fill up gaps. I have noted that good, sound-looking seed of this type is often sterile. The cotyledons rot off in some other cases and the curious thing is that the radical is sound. The plumule, if sound, in these instances, is affected by the cotyledons and the struggle for life soon ends. We seem to have no end to the difficulties among the Spencer type of sweet peas, but, after all, this only makes us more determined to have these desirable flowers.

The best of them, like other things in this world, are often of delicate constitution, and need to be well nursed in infancy. The nursery, therefore, must be of the best. It will be obvious that I lay stress on the radical and plumule (root and growth) getting as quickly as possible from their unhealthy environment. Prepare a light, open compost and have a little sifted charcoal and old lime rubble to lay the seed on (just a mere snuff of it), and immediately under that should be old, sweet leaf-mould. This is an ideal arrangement. Only just cover the seeds with sweet open soil. That, perhaps, is all you can do to "save a life," Further, chip every seed on the back, with a sharp knife, prior to sowing. The creams, whites, and lavenders may not need this care, but it does no harm, and everything must be done to induce rapid germination. Having acted as directed, place the pots or boxes in gentle heat until the plants are an inch high, keeping them near the glass, and then gradually harden off.

It is difficult to account for the peculiarity in the seeds of the type. Too much inbreeding suggests itself as a cause, but that failing should be natural to the old type from whence it sprang.

Variety of colour in an exhibition collection is often forgotten. Pinks, and there are many charming tones of this shade, are usually overdone in collections of six or twelve varieties. I do not like to interfere with individual tastes, as there is too little individuality already, but long tables of multitudes of pink sweet peas look insipid in an exhibition. Just a word therefore on that point in conclusion. I have noticed that sweet peas like Menie Christie and Rosie Adams draw the judge's eye to an exhibit. They are "telling" colours. Few exhibitors used them last year, but some of the novelties are already sold out. In addition to the two mentioned the following are procurable, and would give a rich and varied display: Etta Dyke, pure white; Mrs. A. Malcolm, cream: Constance Oliver, cream ground flushed deep pink; Mrs. Hardcastle Sykes, blush; Helen Lewis, orange and soft rose pink; John Ingman, rosy carmine; Anna Lumley, maroon; Frank Dolby, lavender; Mrs. A. Ireland, bi-colour; Mrs. C. W. Breadmore, cream, picotee-edge pink, and The Marquis, mauve; Menie Christie is magenta, and Rosie Adams gives a peacock-blue effect when bunched.

A. Malcolm.

Town House, Duns.

WORK FOR THE WEEK.

◆

THE ORCHID HOUSES.

EAST INDIAN ORCHIDS.—The various species of ærides which were at one time so prominent in all orchid collections are now but seldom seen. Like many other worthy kinds, they have for a time to suffer a period of neglect. The various species form a most interesting and desirable class of plants, and are suitable for an ordinary plant stove, and, therefore, more suitable for general cultivation than many of the popular orchids of to-day. The allied vandas, of the V. tricolor section, the saccolabiums, and rhynchostylis are also amenable to similar treatment. The noble growth of well-cultivated vandas always commands admiration, even when the plants are not in flower, and where they are grown successfully in any quantity it is rarely indeed that flowers are absent from February until November, as most of the strong plants produce more than one flower scape during this period.

POTTING.—Practically the whole of these orchids are now showing signs of renewed vitality, so that any repotting necessary should be attended to without delay. It is unnecessary that they should be annually repotted, unless, in the case of vandas and ærides, they have become leggy from the loss of their basal leaves. Removal of a portion of the old potting compost, and adding in its place some fresh growing material will usually suffice. In cases where repotting is necessary, it is advisable to thoroughly water the plants before turning them out of their pots. By this means the roots which have attached themselves to the sides of the receptacles are more readily removed. When a plant has been turned out of the pot the stem may be shortened to the desired length, or so much may be removed as the roots will permit. A stick sufficiently strong to support the plant should then be attached. The plant may then be put in the centre of the pot, and, after the roots have been arranged, fill in with plenty of clean crocks and chopped sphagnum moss, finishing off the surface with about an inch deep of chopped sphagnum moss, pressing it firmly. The plants repotted should be watered with rain water, thoroughly wetting the compost through. After repotting, the atmosphere of the house should be kept charged with moisture, and the temperature retained at 70 degrees.

SACCOLABIUMS, the smaller-growing vandas, and rhynchostylis are suitable plants to grow suspended in baskets or pans. The thick-rooted varieties should not be disturbed for repotting more frequently than is absolutely necessary; all dead and decaying matter should be carefully removed, and when this has been done see that the drainage is in order, as the plants require abundance of root moisture when in active growth; stagnation must therefore be guarded against. In place of the material thus removed use chopped sphagnum mixed with sufficient sand to render the compost porous. The whole of this section are benefited by being sprayed whenever the outside conditions permit during the growing season.—H. J. Chapman, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

CONSERVATORY.—From now onward for a month or two there will be no lack of material to keep the conservatory gay, in fact, at no other time have we better material to pick from, as the majority of bulbs will be now at their best, or nearly so, as well as lilacs, azaleas (Indian and mollis), and many other plants, making a much better and brighter show now they have not to be forced so hard

FIRING.—Now that the sun begins to exert a little more power during the day it will be wise to keep an eye on the stoking, and see that those in charge of it have the fires banked off early in the morning when there are signs of a bright day. There is nothing more prejudicial to the well-being of plants than an excess of fire heat, particularly when it is not really necessary, and freshly potted plants feel it more than those that are well established. Care must again be exercised in the afternoon, so as to have the pipes nicely warm again before the sun goes down, or else a quick drop in the temperature will have equally as bad results, and with a rapidly falling temperature outside, it then needs much firing to bring the houses up to their proper temperature again. Shut off the fires early, and start them early again.

CHRYSANTHEMUMS.—These, if put in early in January will now require potting on into large 60's or 54-sized pots, using an open compost of loam, leaf-soil, and sand, with a little bonemeal and oyster shell added; pot them fairly firm, and place them in a frame or on the shelf in a cool house, where they can be kept close for a few days; syringe on all fine days, and as they make roots give them a little air, increasing it gradually until, on fine warm days, the lights may be entirely removed. The present is a very good time for inserting cuttings of the decorative and single varieties, and it will be found that they will root very quickly just now by following the instructions given in the calender for January 16.

PROPAGATION.—Continue the propagation of fuchsias, heliotropes, streptosolens, and other greenhouse plants as cuttings can be secured, not forgetting to pot early batches that are already rooted. Various seeds can now be sown, such as those of celosias, torenias, celsias, annual carnations, grevilleas, clarkias (for pots), etc., etc. These latter make fine decorative plants in pots, and may be had in bloom right through the summer. I usually raise a small batch in the autumn, following these up by a sowing now, and another in a month's time, using the varieties Carnation Flaked and Double Rose. It is best to sow in a pot or pan, and pot the seedlings singly into 60's as soon as big enough to handle, transferring them later into either 48's, 32's, or 24's, according to the size of plant required. The real secret of success with these plants is to grow them on very quickly in the young stage, and harden them off just before they come into bloom; in this way they make fine shapely plants, particularly well adapted for the embellishment of the conservatory or greenhouse.—Thomas Stevenson, Woburn Place Gardens.

STOVE PLANTS.

CROTONS.—At this season cuttings will root freely in the propagating pit or under bell-glasses, and well-coloured tops can be successfully taken off by the process known as ringing. By simply making a slight insertion right round the stem with a sharp knife, and covering this with moss, roots will soon be produced, and when the moss is fairly well filled the tops can be taken off below the moss and potted. Good narrow-leaved varieties such good forms as angustifolius; medium forms, such as Sunbeam, and large-leaved and large varieties such as Emperor Alexander. The distinct character of growth and beautiful foliage render them of special value for decorative purposes. They can be successfully cultivated with or without bottom heat, and in a compost consisting of three parts loam, one part peat, and one part leaf-soil, with sand added. They should have a light, warm position near to the glass, be given free and frequent syringing, and when well rooted be watered liberally.

THYRSACANTHUS RUTILANS. — Cuttings of the young shoots at this season, when from three to four inches long, root freely. When well grown, this elegant plant is a distinct and attractive object with its long, drooping racemes of scarlet tubular flowers. When grown upon a single stem it is the most attractive, and will succeed well in equal parts of peat, loam, and sand.

GLORIOSAS.—The tubers, which will have been wintered in sand, may now be potted. Strong ones had better be placed in their flowering pots, which may be from 12 to 15 inches in diameter. A good compost is formed with rich loam two parts, partly decayed leaf-mould one part, a little decayed manure, with sand in sufficient quantity to keep the whole porous. Smaller tubers should have smaller pots, and the plants be repotted as they gain strength. Near to the roof glass of the stove is a favourable place in which to grow them.

ACHIMENES are equally effective in pots, pans, and baskets, and to prolong the flower-season start them in batches at different times, placing the tuberous, scaly roots in a mixture of loam, leaf-soil, peat, and sand, and cover with a thin layer of soil. Start them in a temperature of about from 65 to 70 deg., afford plenty of light by placing them near to the glass, which should be clean. Water carefully until well rooted, and a very moist atmosphere after top growth has been made and much syringing are not favourable to the leaves, which become disfigured with brown patches. — William Fyfe, Lockinge Park Gardens.

HARDY FRUITS.

BUD PROTECTION.—Tits and bullfinches, when at all numerous, are very destructive to the buds of gooseberries, and are especially so in many cases to the fruit buds on young apples and pears during the early months of the year, and more so perhaps at the time when the buds are just beginning to push forth. Preventive measures, to be of any use, must be taken in hand before damage is done. We practice dusting the bushes with soot and lime, mixed in equal proportions, during the early morning when the trees are damp, and the wind more still than at other times, repeating this when necessary until the buds are fairly well developed. This plan has invariably been successful, but the practice advocated by Mr. W. Strugnell, on page 61, of spraying the bushes with a nicotine emulsion has much to recommend it, the object being to make trees themselves obnoxious to the birds.

STRAWBERRIES.—Where it was necessary to make nursery beds of the young plants last season, owing to the fresh quarters not being ready for them, no time should be lost in having the ground whereon it is intended to plant well trenched, two spits deep, placing a good dressing of manure between the two layers. When the surface is dry enough to work on give a dressing of wood ashes, and, where possible, some well-decomposed manure, such as that from an old hotbed, forking it well into the soil. As soon as the weather is fit for planting put the plants out two feet apart each way, or, if preferred, plant them one foot from each other in the rows, and the latter two feet apart, removing alternate plants after the first year. Plant firmly, and keep the crowns as nearly as possible to the level of the soil. Strawberry cultivation varies very much according to the nature of the soil on which they are grown. On our heavy wet soil we have tried them in several different ways, but none has proved so satisfactory as when we have treated them practically as biennials. We force several hundred plants each season, and from these we select about eight hundred of the best and healthiest plants, arranging them two feet apart all ways on a piece of well-prepared land as soon as they have been properly hardened off. These produce a heavy crop of fruits the next season, and are afterwards dug up and destroyed. For producing choice dessert fruits we layer the runners in pots as early in the season as possible, and plant them out as soon as the pots are full of roots on a piece of good land. In the following season these produce extra fine fruits. We leave them for another year, when they are destroyed. Royal Sovereign is the variety we depend upon largely, but The Leader, Mentmore, Givon's Prolific, Reward, Bedfordshire Champion, The Bedford, Progress, Latest of All, and the Latest do well on our stiff soil.—Geo. Woodgate, Rolleston Hall Gardens.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

Royal Horticultural Society.

There was a very fine exhibition at the Royal Horticultural Hall on Tuesday, February 23, and it was an unusually varied one. Despite the extreme cold of the early morning, and a rather heavy fog during the greater part of the day, the attendance was very good throughout the afternoon. Apples and oranges, primulas and carnations, forced shrubs and early hardy flowers, formed the great attractions, but paintings of flowers, and horticultural sundries also lent beauty and interest to the meeting.

FLORAL COMMITTEE.

Messrs. Jas. Veitch and Sons, Chelsea, were extensive exhibitors on this occasion. In one group they had forced lilacs as a background to handsome, freely flowered specimens of The Countess (white), arboreum Wellsianum (pink), and Handsworth Early Red (rosy-red) rhododendrons. In another display they had the white-flowered Kalanchoe Dyeri, the graceful Crowea angustifolia, Coleus thyrsoideus, and the greenhouse rhododendron Triumphans. Yet another exhibit from Chelsea consisted of choice Chinese primulas, including His Majesty (deep crimson), Fringed White, Crimson King, etc.; and a fine lot of pure white, crimson, rose, lilac, and salmon coloured cyclamens, both plain and fringed forms being displayed to great advantage. Messrs. H. Cannell and Son, Swanley, contributed a very bright exhibit of stellate and Chinese primulas. The former were particularly bright and free-flowered, notably such varieties as Scarlet Gem, Lady Emily, Countess of Radnor—very fine crimson, Scarlet, Unique, Blue Lady, White Spray, Chameleon, and Red Rover. Among the larger flowered varieties one stood out conspicuously by reason of the fine form and substance of its flowers, and their brilliant crimson-scarlet hue, this was Mr. John Ward. Mrs. L. Raphael and Moonlight were other beautiful varieties.

A very beautiful group of Richardia Elliottiana, the golden arum lily, was staged by Mr. W. L. Farmer, gardener to Mrs. Lascelles, Highams, Windlesham, Surrey. There were nearly one hundred of the fine yellow spathes, and in several instances the inflorescences were double spathed, and in some the yellow colouring had entered the leaves also. The group was evidence of great cultural skill, and it was greatly admired. A very beautiful display of forced Azalea mollis, Prunus triloba, lilacs, Staphylea colchica, magnolias, Forsythia suspensa, Pyrus Malus in variety, and spiræas, was arranged with great taste by Messrs. R. and G. Cuthbert, Southgate, Middlesex. The central group of the renowned Anthony Koster azalea was very brilliant, and proved a great attraction.

Messrs. T. S. Ware, Lim., Feltham, showed a collection of encrusted saxifrages, with snowdrops, hardy cyclamens, early irises, adonis, and other pretty early flowers. Messrs. W. Cutbush and Son, Highgate, had a large display of forced flowering shrubs, a group of beautiful early irises, daffodils, hardy primulas, etc., and a charming exhibit of perpetual carnations, all very tastefully disposed. Mr. F. Herbert Chapman, Rye, Sussex, showed a very delightful little lot of seedlings of Cyclamen ibericum, some of them showing evidence of hybridity. With these were some pretty irises of the reticulata group, several seedling freesias, and the yellow Iris Danfordiæ. A very beautiful group of perpetual carnations was staged by Mr. H. Burnett, Guernsey, in which Mrs. H. Burnett, Mikado, Marmion, and Britannia were grandly shown, the colours being very bright and clean.

Mr. G. Reuthe, Keston, Kent, showed rare rhododendrons, pans of snowflakes and snowdrops, and of Iris histrio, I. histrioides, and crocuses in great variety and beauty. He also had daphnes, camellias, hardy cyclamens, encrusted saxifragas, and many other beautiful and interesting little plants. Messrs. Barr and Sons, Covent Garden, had a pretty exhibit of early daffodils, some charming lachenalias, and crocuses, the new Freesia Rose Queen (A.M.), and the winter-flowering Cheiranthus Kewensis. Mr. W. H. Page, Tangley Nursery, Hampton, had another very pretty exhibit of beautiful vases of Lilium longiflorum, L. speciosum rubrum, Victoria daffodils, and Mrs. T. W. Lawson, Winsor, Enchantress, Governor Roosevelt, My Maryland, White Perfection, and Britannia carnations, all very fine in size and colour. Mr. Robt. Sydenham, Tenby Street, Birmingham, contributed lily of the valley grown in moss fibre. Carnations in great variety and beauty, set up in vases of varying size, and also in hanging baskets, formed the greater part of the display made up by Messrs. Hugh Low and Co., Bush Hill Park, Enfield; azaleas, acacias, etc., were also freely shown by this firm.

Delightful flowers of Richmond and Joseph Lowe roses, fine in form, stem, and colour, were shown by Mr. George Mount, Canterbury, and few exhibits attracted so much attention.

ORCHID COMMITTEE.

Messrs. Sander and Sons, St. Albans, were represented on this occasion by a fine exhibit of orchids. Phalænopsis Schilleriana was well shown, and in the group there were excellent examples of Cymbidium insigne Sanderæ, Saccolabium bellinum, Calanthe hololeuca, Odontoglossum Harryano-crispum, O. pulchellum majus, O. Hunnewellianum, Cattleya Trianæ, Cœlogyne cristata alba, and various cypripediums. Messrs. Cypher and Sons, Cheltenham, showed several good dendrobiums and cypripediums, Miltonia Bleueana, and the rare Masdevallia macrura and M. chimæra. Messrs. J. and A. McBean, Cooksbridge, set up some fine forms of Cattleya Trianæ and several choice odontoglossums. Messrs. Hugh Low and Co., Bush Hill Park Enfield, showed Cymbidium Woodhamsianum, Odontoglossum crispum Carmania, etc. Mr. Black, gardener to R. G. Thwaites, Esq., showed several seedling dendrobiums, that included D. atro-Brymerianum (A.M.), an interesting cross between D. atroviolaceum and D. Brymerianum. Mr. Tracey, Twickenham, sent Cycnoches peruviana that gained an A.M.

Some very interesting orchids were exhibited by Mr. Collier, gardener to Sir J. Colman, Bart., Gatton Park, Surrey; these included Bulbophyllum comosum, Cirrhopetalum retusiusculum, C. Mastersianum, and the beautiful Dendrobium Lady Colman (A.M.). Mr. G. F. Moore, Chardwar, Bourton-on-the-Water, brought up several fine cypripediums, C. Curte-manni and C. Bridget magnificum securing each an A.M.; the latter is very fine, the red-purple colouring in the petals being very effective. Læliocattleya Pizarro Westonbirt var. (F.C.C.) and Cattleya Trianæ Mooreana (F.C.C.) were shown by Mr. H. G. Alexander, orchid grower to Lieut.-Colonel Holford, and the last named was a grand flower.

M. Maurice Mertens, Mont St. Amand, Ghent, brought over a wonderful lot of beautiful odontoglossums, including O. amabile, O. ardentissimum, O. laudatum, and numerous hybrids. Mr. De Barri Crawshay, Rosefield, Sevenoaks, sent several odontoglossums, notably O. Zena, a cross between O. sceptrum and O. Harryanum; and O. cariniferum (B.C.). The fine Cymbidium Woodhamsiensis (A.M.) was shown by Messrs. Armstrong and Brown, Tunbridge Wells. In the group of orchids brought up by Messrs. Charlesworth and Co., Haywards Heath, we made special note of the bright Odontioda Keighleyense (A.M.), O. Lutetia (F.C.C.), Lælia-cattleya Myra, Miltonia Bleueana, Brasso-cattleya Cooksoni, and Trichopilia suavis.

FRUIT COMMITTEE.

Messrs. T. S. Rivers and Sons, Sawbridgeworth, put up a wonderful and fine exhibit of home-grown oranges, and the display was a great feature of the show. The pot trees of various sizes, carrying golden, ripe fruits, attracted a great deal of attention, while the picked fruits and the heavily-laden branches were the subjects of a great deal of favourable comment. Achilles, St. Michaels, Jaffa, Brown's Orange, Sustain, and Navel oranges were splendid, while the citrons, shaddocks, and limes were no less wonderful. The exhibit at once demonstrated the desirability of home-grown oranges, and in gardens of some size they will doubtless ere long be as regularly grown as forced strawberries.

Mr. R. Bullock, gardener to O. P. Serocold, Esq., Taplow Hill, Taplow, Bucks, showed good dishes of Baxter's Pearmain, Tower of Glamis, Cox's Orange Pippin, Cox's Pomona, Warner's King, and other good apples.

A Lucky Sixpence.

This tells you how for sixpence
You can put yourself in the way
Of preventing mental worry and physical strain.
If you feel a breakdown in health
Spend the sixpence and be convinced.

Sir James Crichton-Browne has pointed out that one of the main causes of such physical and mental degeneracy as exists amongst us is bad or insufficient food.

This is unfortunately but too true, as the proprietors of Vi-Cocoa have been pointing out for years, and now food faddism has reached a point at which it is seriously affecting the health of the community. The craze for getting thin is on a par with race suicide.

Vi-Cocoa is the most perfect flesh-forming food beverage ever placed before the public.

It not only possesses highly nutritious and sustaining properties, but it is also soothing, acts as a tonic, and considerably assists weak digestions.

Vi-Cocoa — a packet of which can be obtained everywhere for the small sum of sixpence—is in a great measure self-digesting, and exceeds tenfold in nutrient and sustenant power any other food beverage, and it will steadily build up your body to a healthy condition if taken regularly night and morning.

You can try it free of expense. Write to Vi-Cocoa, 12, Henry Street, London, W.C., for a dainty sample tin of Dr. Tibbles' Vi-Cocoa free and post paid. It is a plain, honest, straightforward offer. It is done to introduce the merits of Vi-Cocoa into every home.

Messrs. W. Seabrook and Son, Chelmsford, put up a fine collection of apples, showing splendid fruits of Dutch Mignonne, The Queen, Beauty of Kent, Bismarck, Sturmer Pippin, Dumelow's Seedling, King of the Pippins, etc.

Mr. W. Poupart, Fernleigh Orchards, Twickenham, showed some splendid bottled fruits, putting up several dozen bottles of plums, peaches, nectarines, currants, raspberries, mulberries, cherries, and apricots, all very clear and bright, and in glass-stoppered bottles. Mrs. Miller, Mayleen, Marlow, showed chutney and fruit jellies.

Mr. J. Watkins, Park Farm Orchards, Maplehurst, Horsham, led for one dish of a dessert apple with Claygate Pearmain; and Mr. H. G. Wadlow, Marylands, Dogsthorpe, Peterborough, was second with Cox's Orange Pippin.

Messrs. Jas. Veitch and Sons, Chelsea, secured first prize for six dishes of dessert apples with excellent examples of Sturmer Pippin, Northern Spy, Lord Hindlip, Dutch Mignonne, Reinette du Canada, and King of Tomkins County; Messrs. W. Seabrook and Son, Chelmsford, were awarded second prize. In each case a silver Banksian medal was also awarded.

There were eleven entries in the class for four dishes of dessert apples, and first prize fell to Mr. H. Markham, gardener to Viscount Enfield, Wrotham Park, Barnet, for well-preserved, bright fruits of May Queen, Cox's Orange Pippin, Golden Winter Pearmain, and Baumann's Red Reinette; Mr. J. Whittle, gardener to Colonel Boston, Cheveney Hunton, Kent, second with Christmas Pearmain, Calville Rouge, Barnack Beauty, and Melon Apple.

CERTIFICATES AND AWARDS.

First-class Certificate:—

To Cattleya Trianæ Mooreana, and to L.-c. Pizarro Westonbirt var., from Lieut.-Colonel Holford, Westonbirt, Tetbury, Gloucester.

To Odontioda Lutetia, from Messrs. Charlesworth and Co., Haywards Heath.

To apple Barnack Beauty, from Mr. Poupart, Marsh Farm, Twickenham.

Award of Merit:—

To Cycnoches Peruviana, from Mr. H. A. Tracey, Twickenham.

To Cymbidium Woodhamsiense, from Messrs. Armstrong and Brown, Tunbridge Wells.

To Dendrobium atro-Brymerianum, from Mr. R. G. Thwaites, Chessington, Putney.

To Dendrobium Lady Colman, from Sir J. Colman, Bart., Gatton Park, Reigate.

To Cypripedium Bridgei magnifica and C. Curtemanni, from Mr. G. F. Moore, Chardwar, Bourton-on-the-Water.

To Odontioda Keighleyensis, from Messrs. Charlesworth and Co., Haywards Heath.

To Freesia Rose Queen, from Messrs. Barr and Sons, King Street, Covent Garden.

MEDALS.

Silver-gilt Knightian.—To Messrs. T. S. Rivers and Sons, Sawbridgeworth, for oranges.

Silver-gilt Flora.—To Messrs. Sander and Sons, St. Albans, for orchids; Miss Josephine Gundry, Foots Cray, Kent, for floral studies in water-colours; Messrs. R. and G. Cuthbert, Southgate, for forced shrubs, Messrs. Wm. Cutbush and Son, Highgate, for forced shrubs, etc., Mrs. Lascelles, Windlesham, for Richardia Elliottiana, Messrs. Jas. Veitch and Sons, Chelsea, for primulas, cyclamens, etc.

Silver Flora.—To Messrs. Charlesworth and Co., Haywards Heath, for orchids; Messrs. Hugh Low and Co., Enfield, for carnations, etc., Mr. H. Burnett, Guernsey, for carnations, Mr. W. H. Page, Hampton, for carnations and liliums, Messrs. H. B. May and Sons, Edmonton, for ferns and primulas.

Silver Knightian.—To Mr. Bullock, gardener to O. P. Serrocold, Esq., Taplow, for apples.

Silver Banksian.—To Messrs. H. Cannell and Sons, Eynsford, for primulas; Mr. G. Mount, Canterbury, for roses; Messrs. J. Peed and Son, West Norwood, for alpines; Messrs. Thos. S. Ware, Lim., Feltham, for alpines; Messrs. J. Cypher and Sons, Cheltenham, for orchids; Mr. Maurice Mertens, Mont St. Amand, Ghent, for orchids.

Bronze Banksian.—To Mr. G. Reuthe, Keston, Kent, for hardy plants.

Birmingham Gardeners' Association.

Under the auspices of the Midland Carnation and Picotee Society a meeting was arranged to be held at the lecture-room of the Birmingham Gardeners' Association, with the view of promoting the interests of the Carnation Society. Mr. Robert Sydenham presided over a large assembly of the members and their friends, to listen to the dual pronouncements of Messrs. A. R. Brown and C. H. Herbert, two well-known Birmingham experts in the cultivation and exhibition of the carnation and picotee. The addresses were given verbally, and were restricted to fifteen minutes each, so as to afford ample time for the discussion, which was participated in both by professionals and amateurs. Mr. A. W. Jones, another noted carnation grower, also gave considerable instructive information.

There was an animated "passage of arms" in reference to "dressed" and "undressed" blooms on the exhibition table, the general opinion being that there is room for both, the time-honoured system suitable for displaying them in the highest state of perfection requiring a certain amount of "dressing," but not necessarily so for decorative purposes. Mr. Herbert, in alluding to the "perpetual" or tree carnation, opined that in the course of time a cross between these and the border varieties would become the popular flower.

Mr. Robert Sydenham, in adverting to the essentials necessary for the attainment of success in the cultivation of the carnation, especially for exhibition purposes, instanced his own determination and fixity of purpose when striving to secure high rank on the exhibition table. In desiring to augment the membership of the Carnation Society Mr. Sydenham intimated that for every five shillings subscription he was prepared to present a dozen young plants in pots of the leading varieties, chiefly with the view of encouraging the cultivation of the carnation amongst amateurs. The hon. secretary, Mr. Thomas Humphreys, Botanical Gardens, Edgbaston, will be glad to receive the names of new members.

Chester Paxton Society.

At the third meeting of the winter session Mr. N. F. Barnes, F.R.H.S., head gardener to his Grace the Duke of Westminster, Eaton, delivered to the members an exceedingly interesting lecture entitled "A Visit to the Great Centenary Flower Show at Ghent, with Notes by the Way." The chair was occupied by Mr. Robt. Wakefield. The lecturer gave some interesting particulars of his travels to Ghent, and proceeded to describe its history, following this by descriptions of the beautiful cathedral and many other public buildings in Ghent. These were graphically illustrated by beautiful lantern slides. He also gave a short outline of the history of the Ghent Horticultural Society, which had promoted the exhibition, and which, like others of its kind, had a very humble beginning.

Of the exhibition proper, at which Mr. Barnes officiated as one of the jurors, he mentioned that it was formally opened by the King of the Belgians, and occupied two large buildings, the Casino and the Annexe. Many interesting details were given, and the system of grouping the plants and other exhibits was favourably commented on. The lecturer then very clearly described the many exhibits, the majority of which he was able to indicate by means of lantern slides. Special reference was made to the collections of hippeastrums (or amaryllis) shown by Major Holford, of Westonbirt, and by Messrs. Ker and Sons, of Liverpool. First honours were awarded to the last named, against strong competitors from Belgium and other Continental countries. The collection of orchids staged by Major Holford, and which occupied 300 feet space, was referred to as the finest and most representative in the show; whilst M. Charles Vuylsteke's new odontoglossums were described as one of the most notable exhibits of these beautiful flowers. The lecturer briefly made mention of the many nursery establishments in the neighbourhood of Ghent, from which large importations of plants, such as palms, camellias, azaleas, etc., are regularly made to England.

Mr. Barnes was heartily thanked for his able address by an appreciative audience.

Gardeners' Royal Benevolent Institution.

Under the presidency of Mr. Harry J. Veitch, a largely attended meeting of the committee, which included Mr. W. A. Bilney, the honorary solicitor, was held on February 23, when it was unanimously resolved, "That in view of amendments to the Old Age Pensions Act, which will probably be proposed by the Government during the present session of Parliament, no immediate steps should be taken for the alteration of annuities payable by the institution." At the same meeting six gardeners and two widows of gardeners in urgent need of assistance were granted between them £45 from the "Good Samaritan Fund" as temporary help.

The annual re-union of the Liverpool Auxiliary was held at the Bear's Paw on the 20th inst., and proved again a great success. M. E. Keaney, Esq., deputy chairman of the Parks and Gardens Committee, presided. The hall was charmingly decorated throughout by the kindness of Messrs. E. Webb and Sons, R. P. Ker and Sons, Dicksons, Chester, C. A. Young, and others. Both plants and flowers were in abundance, whilst buttonholes were more conspicuous than usual. The Chairman gave an admirable address on "Municipal Gardening." The arrangements were carried out by Mr. C. A. Young, chairman; Mr. A. J. Crippin, treasurer; Mr. J. Finnigan, musical director; and Mr. R. G. Waterman, secretary.

FORTHCOMING ENGAGEMENTS.

TUESDAY, March 2.—National Amateur Gardeners' Association: Lecture on "Garden Dahlias," by Mr. George Gordon, V.M.H., at 7 p.m.

WEDNESDAY, March 3.—Hampstead Heath Protection Society Annual Meeting: Lecture on "Beautiful Trees and Shrubs," by Mr. George Gordon, V.M.H., at 8.30.

THURSDAY, March 4.—Linnean Society Meeting. Royal Botanic Society; Lecture on "Water Plants," by Dr. Fritsch.

SATURDAY, March 6.—French Horticultural Society of London.

MONDAY, March 8.—United Horticultural Benefit and Provident Society at Royal Horticultural Hall, Westminster: Chair to be taken at 8 o'clock by Mr. C. H. Curtis.

TUESDAY, March 9.—Royal Horticultural Society: Fruit, Floral, and Narcissus Committees meet at 12 o'clock; Lecture by Mr. W. S. Murray on Tulips and the Tulip Mania, at 3 p.m.; Scientific Committee at 4 p.m. Competitive Show of Forced Bulbs.

WEDNESDAY, March 10.—Royal Botanic Society: Fellows' Dinner.

New Catalogue of Gardening Books.—The publishers of the Gardeners' Magazine have prepared a new catalogue of their gardening books, setting out full particulars of the contents of each work. The books, which are thoroughly practical and up-to-date, will be of particular service to those interested in flowers, the greenhouse, or the garden. A copy of the catalogue will be sent post free to any reader who addresses a postcard to the Publisher, The Gardeners' Magazine, 148 and 149, Aldersgate Street, London.

DESTRUCTION OF VERMIN. — Most gardens are pestered with Rats and Mice. Every effort should be made at this time of the year to exterminate them before seeds are sown. Danysz Virus is first rate stuff for killing these vermin. Single tube, 2s.; three tubes, 5s. Post free from DANYSZ VIRUS LTD., 52, Leadenhall Street, Garden Dept., London, E.C.- [Advt.]

For 50 years we have specialised in the construction of Glasshouses, and our name is now regarded all over the country as synonymous with all that is the latest and best in Glasshouse construction. Contracts are undertaken for the erection and heating of

CONSERVATORIES, WINTER-GARDENS, VINERIES,

and all kinds of Glasshouses.
The most recent improvements in Ventilation, Heating and Internal Fittings are introduced.

Plans and Estimates will be sent free on receipt of particulars.
WRITE FOR ILLUSTRATED CATALOGUE, POST FREE.

Recent Contracts include the following:—

His Grace the Duke of Bedford, Woburn Abbey.
His Grace the Duke of Buccleuch.
The Rt. Hon. the Earl of Craven, Coombe Abbey, Coventry.
The Rt. Hon. the Earl of Stamford and Warrington, Dunham Massey Hall, Altrincham.
The Rt. Hon. the Earl of Dysart, Buckminster Park, Grantham.
The Rt. Hon. the Earl of Portsmouth, Hurstbourne Priors.
The Rt. Hon. the Earl of Lathom, Lathom, Ormskirk.
The Rt. Hon. the Earl of Wimborne, Merly House, Wimborne.
The Rt. Hon. Earl Fortescue, Castle Hill, Devonshire.
The Rt. Hon. Lord Hillingdon, Hillingdon Court.
The Rt. Hon. Lord Aldenham, Hilfield, Aldenham.
The Rt. Hon. Lord Dunboyne, Knoppogue Castle, co. Clare.
The Rt. Hon. Lord Hatherton, Teddesley, Penkridge, Stafford.
Sir J. B. Robinson, Park Lane, W. (Conservatory at Cape Town).
Sir Robt. Peel, Drayton Manor, Tamworth.
Sir Philip Chetwode, Oakley Hall, Market Drayton.
Count Gurowski, Woolhampton House, Reading.
C. G. Cunard, Esq., Notgrove Manor, Cheltenham.
Mrs. Geoffrey Lubbock, Broad Oaks, Byfleet, Surrey.
H.M. Board of Works, Glasshouses in Hyde Park.
W. Waldorf Astor, Esq., Hever Castle, Kent.
A. E. Bowen, Esq., Colworth, Sharnbrook.
J. J. Sainsbury, Esq., Broadlands, Haverhill.
Libert Oury, Esq., Holwood House, Walton-on-Thames.
W. Pendle, Esq., White Rose Lane, Woking.
Dr. C. W. Drabble, The Grange, Walton on Thames.
Morgan Jones, Esq., Llanmiloe Mansion, Carmarthen.
F. A. Darwin, Esq., Bolton Lodge, Bolton Percy.
R. K. Fenton, Esq., Dutton Manor, Longridge, Preston.
Jas. D. Crosbie, Esq., D.L., Ballyheigue Castle, co. Kerry, Ireland.
H. K. Rutherford, Esq., Soloms Court, Banstead.
A. T. Cook, Esq., Sennowe Hall, Great Ryburgh, Fakenham.
Col. Le Roy Lewis, D.S.O., Westbury House, Petersfield.
Sir C. Swinfen Eady, Oatlands Lodge, Weybridge. (Quorn Boilers).
Messrs. Bass, Ratcliff and Gretton, "Quorn" Boilers for Heating Offices, etc.
Corporation of Bradford, Conservatories for four Public Parks.
Corporation of Oldham, Conservatories, etc., Alexandra Park.
Corporation of Ashton-under-Lyne, Conservatory at Stamford Park.
Leicestershire County Council (Heating to Council Schools).

LONDON, E.C.

ANSWERS TO CORRESPONDENTS.

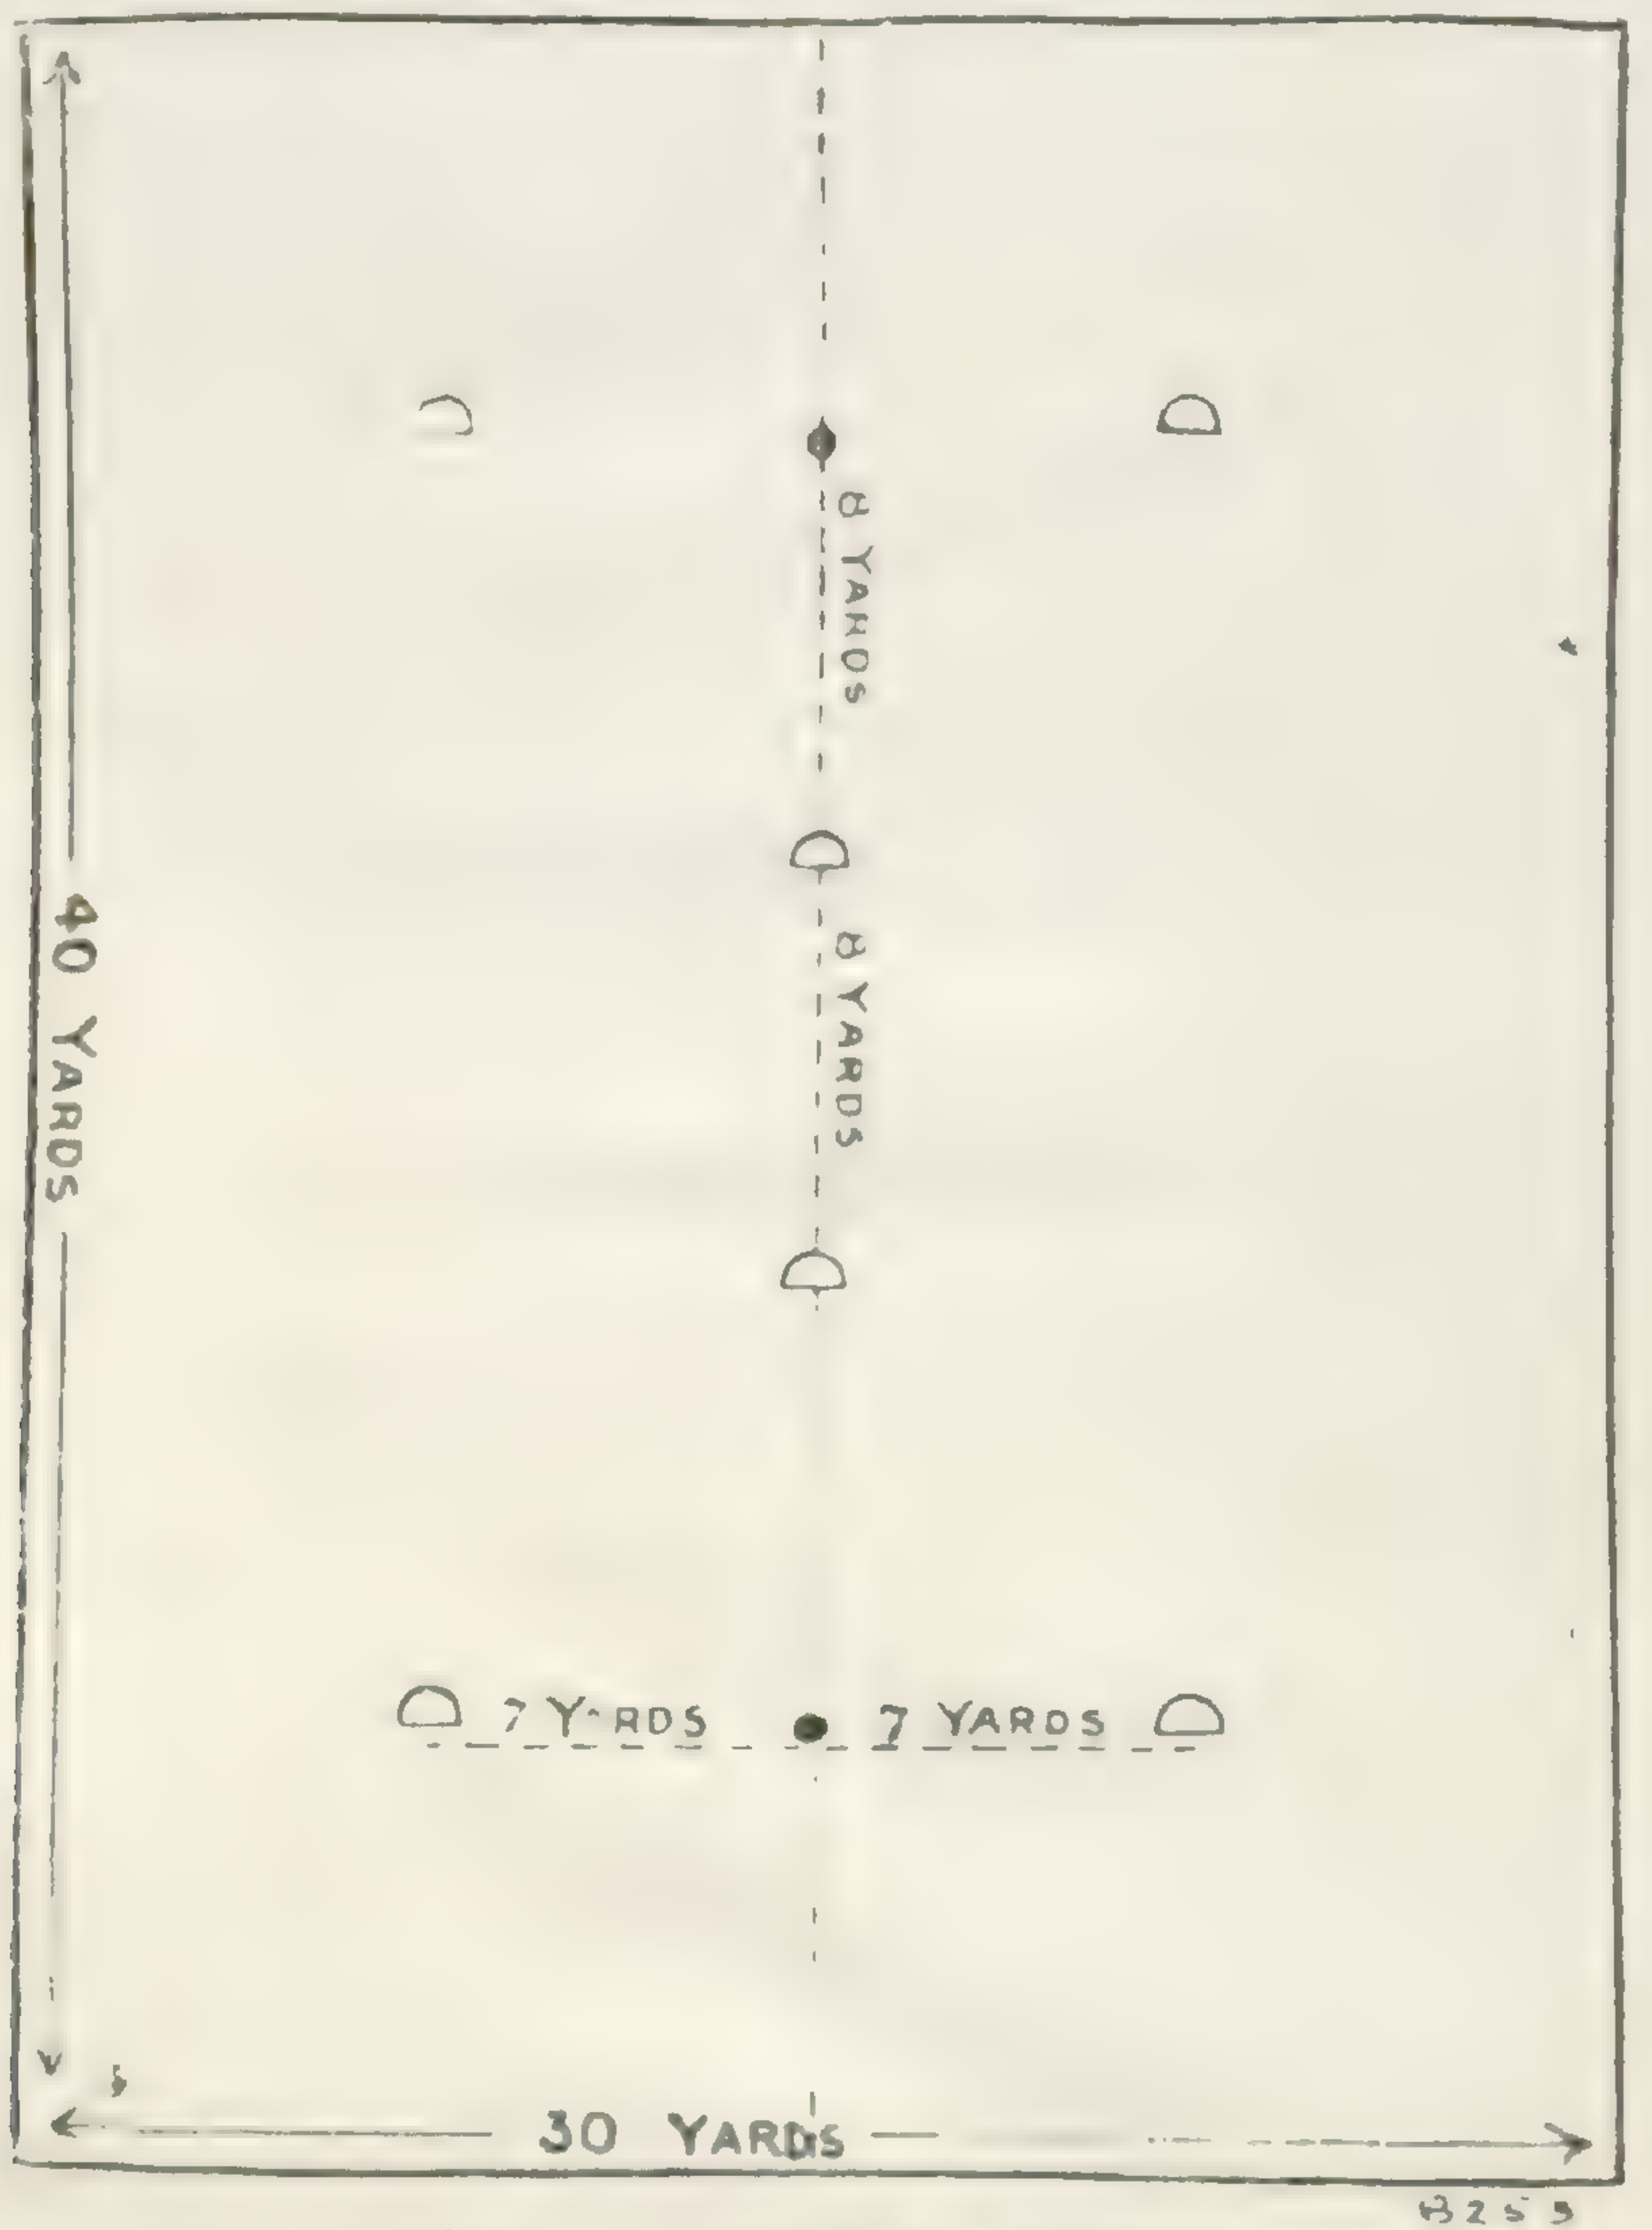
Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

CROQUET LAWN.—A. P. M., Chichester: If the game is to be played in strict accordance with the All England Croquet Club rules, then the lawn should be marked out as shown in the accompanying diagram. Once the measurements have been made, and pegs sunk in the corners and at the points where the hoops and croquet pegs are to be placed, no difficulty will be found in keeping the ground in accordance with regulations. A full-sized croquet ground should be 40 yards long by 30 yards wide. In a line through the centre of the ground two hoops and two pegs are placed, each of the latter being set up eight yards from the end boundary, with the two hoops between them, placed at eight yards from each other, and a similar distance from each croquet peg. The four corner hoops must be placed in line with the pegs, and seven yards from them, as shown in the diagram. Croquet is often played on smaller grounds, consequently, if space is limited, the measurements may be proportionately reduced, or the boundary disregarded. In the latter case, a space of about 26 yards by 16 yards would suffice for the field of play.



PLAN OF CROQUET GROUND.

DRY TENNIS COURT.—B. J., Eccleston: A dry tennis court may be made of tar paving, asphalt, wood blocks, or concrete, and, unless you have special facilities for the work it will be better and cheaper to invite tenders, and have the work done by contract. There is some objection to tar paving because, under very hot sunshine, some parts of it may become sticky, and thus inconvenience the players. Proper asphalt, put down by a firm well acquainted with the work, has a very even, smooth surface, and wears well. Wood blocks, if thoroughly well set, answer well for some time, but there is a danger of uneven wear, and cracking.

MUSHROOM CULTURE.—G. M., Dublin: If the door is in the nine-feet end of the building, and in the centre of the end, your best plan will be to arrange for two flat beds, one on either side, and each 6ft. wide, thus allowing for a 2ft. path down the centre. If the building is a strong one, it would be an easy matter to construct similar beds 4ft. above those on the floor, using angled iron for supports, and sheet iron or stout slates as a base for the beds. The woodwork for the edges of the lower beds should be creosoted, or treated with Stockholm tar some little while before being used. We have not tested the spawn you refer to, but the reputation of the firm is so high that you may safely rely upon the high quality of the material. No. 4 of the Market Gardening Handbooks deals with mushrooms, cucumbers, etc., and you will find it most useful; it can be obtained for 1s. 2d. post free from the GARDENERS' MAGAZINE Office, 148 and 149, Aldersgate Street, E.C.

SPECIALISED OUTDOOR TOMATO CULTURE.—M. T. C., Chelmsford: The special method of tomato culture you refer to was described several years ago in these pages, and it is such an excellent one that we readily publish it again: About the second week in April are secured stout young tomato plants that are just showing their flower buds, and have been grown in a greenhouse. These are planted in a border, which has previously been well prepared by deep digging, and the addition of some old lime rubbish, and allowed to settle. The plants are laid in a little way from the wall, and the stem covered, only the leafy head being left uncovered by soil. Firm planting is practised, and when the work has been completed, the lights from cold frames are tilted, lengthwise, against the wall, the lower edge being secured by the path curb. These lights shelter the tomatoes from cold winds and rains, and they serve as admirable sun-traps. Either end of this improvised shelter is blocked by a triangular board, and other boards are placed over the spaces formed by the abutting ends of the lights, but these are removed, as necessary, during the first few weeks, to afford ventilation, so that the lights themselves need not be moved. At night the lights are covered with felt and mats to keep out frost, and retain the heat accumulated during the day. When the plants increase in height, so as to reach nearly to the point where the light touches the wall, a thick block of wood is placed between the light and the wall, both to afford the plants more head room and provide increased ventilation. The single-stem method of training is adopted, and, consequently, all lateral growths are removed as they appear; and yet not all, i.e., the one that appears nearest the ground line, and points away from the wall, is allowed to extend, and when it is long enough to be so treated, it is "layered," some turf being laid over the stem, and a half brick on the turf to keep things in place. About the time that this secondary growth is laid down the frame lights are removed, and used for melons, cucumbers, etc. Fertilisation is assisted by dusting over the flowers during the middle of the day with a camel-hair brush, or a rabbit's tail, and by this means no difficulty is found in securing a good set, on even the lowest and first cluster of flowers. When three or four clusters have set and the fruits are swelling freely on the bottom cluster, a mulching of half-rotten manure is given. Ample water is now given, but care is taken not to over-water, and, on the other hand, the plants are never neglected, it having been found that irregularity and excess in the supply of water quickly exhausts the virtue of the mulch, and also causes the fruits to crack. When laden with fruit and foliage each plant needs about a pailful of water at each watering in an average season. The plants are never sprayed overhead, as this would encourage leaf growth, and would, moreover, rob the wall of a good deal of heat. It might be imagined that the encouragement of a lateral from the base would interfere with the progress and ripening of the lowest fruits on the main stem, but in practice this is not so, as the three lowest clusters will ripen before the lateral, trained at a moderate angle from the wall, is sufficiently large to intercept the sunlight. Nothing is left to chance. Each fruit cluster is slung, by means of raffia, to the leaf stem above, so that as the fruit swells it does not fall, and cause the flower stem to "kink," and so retard the flow of sap. This "slinging" is done as soon as the fruits have formed. The lower leaves are shortened during August, but not on the part of the plant where fruits are developing. The cost of this method is small, the prospects considerable, and the results are certain if reasonable care is taken, and a wall facing south or south-west is chosen for a site.

GRASS EDGE CUTTER.—C. C., Salisbury: There is a machine, or machines, on the market designed for the special purpose of cutting the edges of lawns and grass verges. The one we have seen looks like a small lawn mower, with six short blades set at one side so as to cut down vertically. Of course, the blades overhang the edge, and the edge of the roller of the machine can be kept on the true line of the margin. There is a special arrangement for raising or lowering the cutting blades according to the thickness of the turf. Your best plan will be to write for particulars of such a machine to those firms which are advertising lawn mowers in our columns.

NAMES OF PLANTS.

D. L., Conway.—1, Abies Nordmanniana; 2, Juniperus chinensis; 3, Cerasus Laurocerasus.

W. R., Mitcham.—1, Erica carnea; 2, Iris reticulata; 3, Cestrum elegans.

P. J., Aylesbury.—1, Acacia longifolia; 2, A. armata.

G. D., Exeter.—1, Cattleya Trianæ; 2, Arabis albida variegata; 3, Sibthorpia europæa.

TWO VALUABLE GARDEN GUIDES

"A book which both inspires and helps: its scheme and arrangement are excellent."—*Nottingham Guardian.*

SUTTON'S RINGLEADER MELON.
One of the finest Melons we have introduced during our long experience.
Per packet, 1s. 6d., post free.

Mr. C. Beckett, The Gardens, Chilton Lodge, writes:—"Melons have given the greatest satisfaction to my employer. One fruit of your Ringleader exhibited at the Temple Show weighed 9¼lbs.; while three fruits from one plant averaged 7lbs. each."

SUTTON AND SONS, THE KING'S SEEDSMEN, READING.

NOW IS THE TIME TO PLANT
(the best time of the whole year)
KELWAY'S BEAUTIFUL BLUE DELPHINIUMS.

Hardy, and flourishing in every garden, they are the STATELIEST of PERENNIAL PLANTS for borders or beds; these celebrated improvements are invaluable for their introduction of that precious colour—blue—in masses to the garden. KELWAY and SON developed this race, and they should be procured direct from the Royal Horticulturists, Langport.

KELWAY'S IMPROVED DELPHINIUMS are now ready, strong plants, in choice named selections. Collection "B," 15s. per doz. Collection "D," 42s. per doz. Delivery free for remittance with order. KELWAY and SON, The Royal Horticulturists, Langport, Somerset.

FRANCO-BRITISH EXHIBITION, 1908. ONE of the ONLY THREE Gold Medals (or Higher Awards) (open to the whole world for permanent exhibits) awarded by the International Jury, and confirmed by the Governing Council was awarded to Kelway and Son; vide the AUTHORISED LIST published in the Press.—KELWAY and SON, Langport, Somerset.

FOR PRESENT PLANTING.

PLANTERS of FRUIT TREES should write for our fully descriptive catalogue and supplement, 6d., post free; and gratis to customers.

Well-ripened trees of all kinds, and our large, developed specimens of Vines, Figs, Peaches, and Nectarines, are especially good.

An inspection solicited.

Miss SAUL, Wainfleet, Lincolnshire.

TO-DAY! AND FOR YEARS AND YEARS PAST the XL ALL Specialities are and have been the best on the market. Where is the Gardener who does not pin his faith to one or the other of these celebrated Insecticides or Fertilisers? XL ALL FERTILISER has pleased all who have used it this season. The Sales of XL ALL FUMIGATOR prove that it is more popular than ever. XL ALL LIQUID NICOTINE INSECTICIDE is always spoken of by gardeners and growers as the most deadly to Mealy Bug, Thrip, etc. XL ALL WINTER WASH for dormant Trees acts like magic, clearing the Trees and Bushes of all Insects' Eggs, Moss, and Fungoid Growths. XL ALL LAWN SAND, a weed eradicator and fertiliser for weedy and poor lawns. XL ALL WEED KILER used once a year "No weeds can live." Please ask your Nurseryman, Seedsman, or Florist for a copy of my small pink list, giving particulars of these and many other XL ALL Preparations, which can be obtained from the Horticultural Trade throughout the World. G. H. RICHARDS, Manufacturer and Patentee, 234, Borough High Street, London, S.E.

WEBBS' NEW FAVOURITE MELON.

Green fleshed. **2/6** per packet, post free.

"Your New Favourite Melon has been greatly admired. I cut one fruit off a plant that bore four and it turned the scale at 7lbs. The flavour was delicious."—Mr. C. Cox, The Gardens, Wal Hall.

WEBBS' NEW EPICURE MELON.

Scarlet fleshed. **2/6** per packet, post free.

"Webbs' Epicure Melon is a grand variety, of splendid flavour. I was awarded First Prize with it at Stoke Show."—Mr. C. Frost, Gardener to L. H. Hanbury, Esq.

The King's Seedsmen,
WORDSLEY, STOURBRIDGE.

GLADIOLI.

The great range and almost endless combinations of colour of the Gladiolus is hardly equalled by any other flower.

OUR HYBRIDS possess the most exquisite colourings, with blooms of exceptional size, and are borne on large and vigorous spikes, while so great is the diversity that purchasers of 100 corms will get but few duplicates. We consider them equal to any named sorts, and the cost is about one quarter.

WINNERS OF MANY AWARDS DURING 1908.

THE

CORINIUM HYBRIDS, Mixed.

1st size, strong flowering corms, per 100, **15/-;** per dozen, **2/-**.

Carriage and Packing Free.

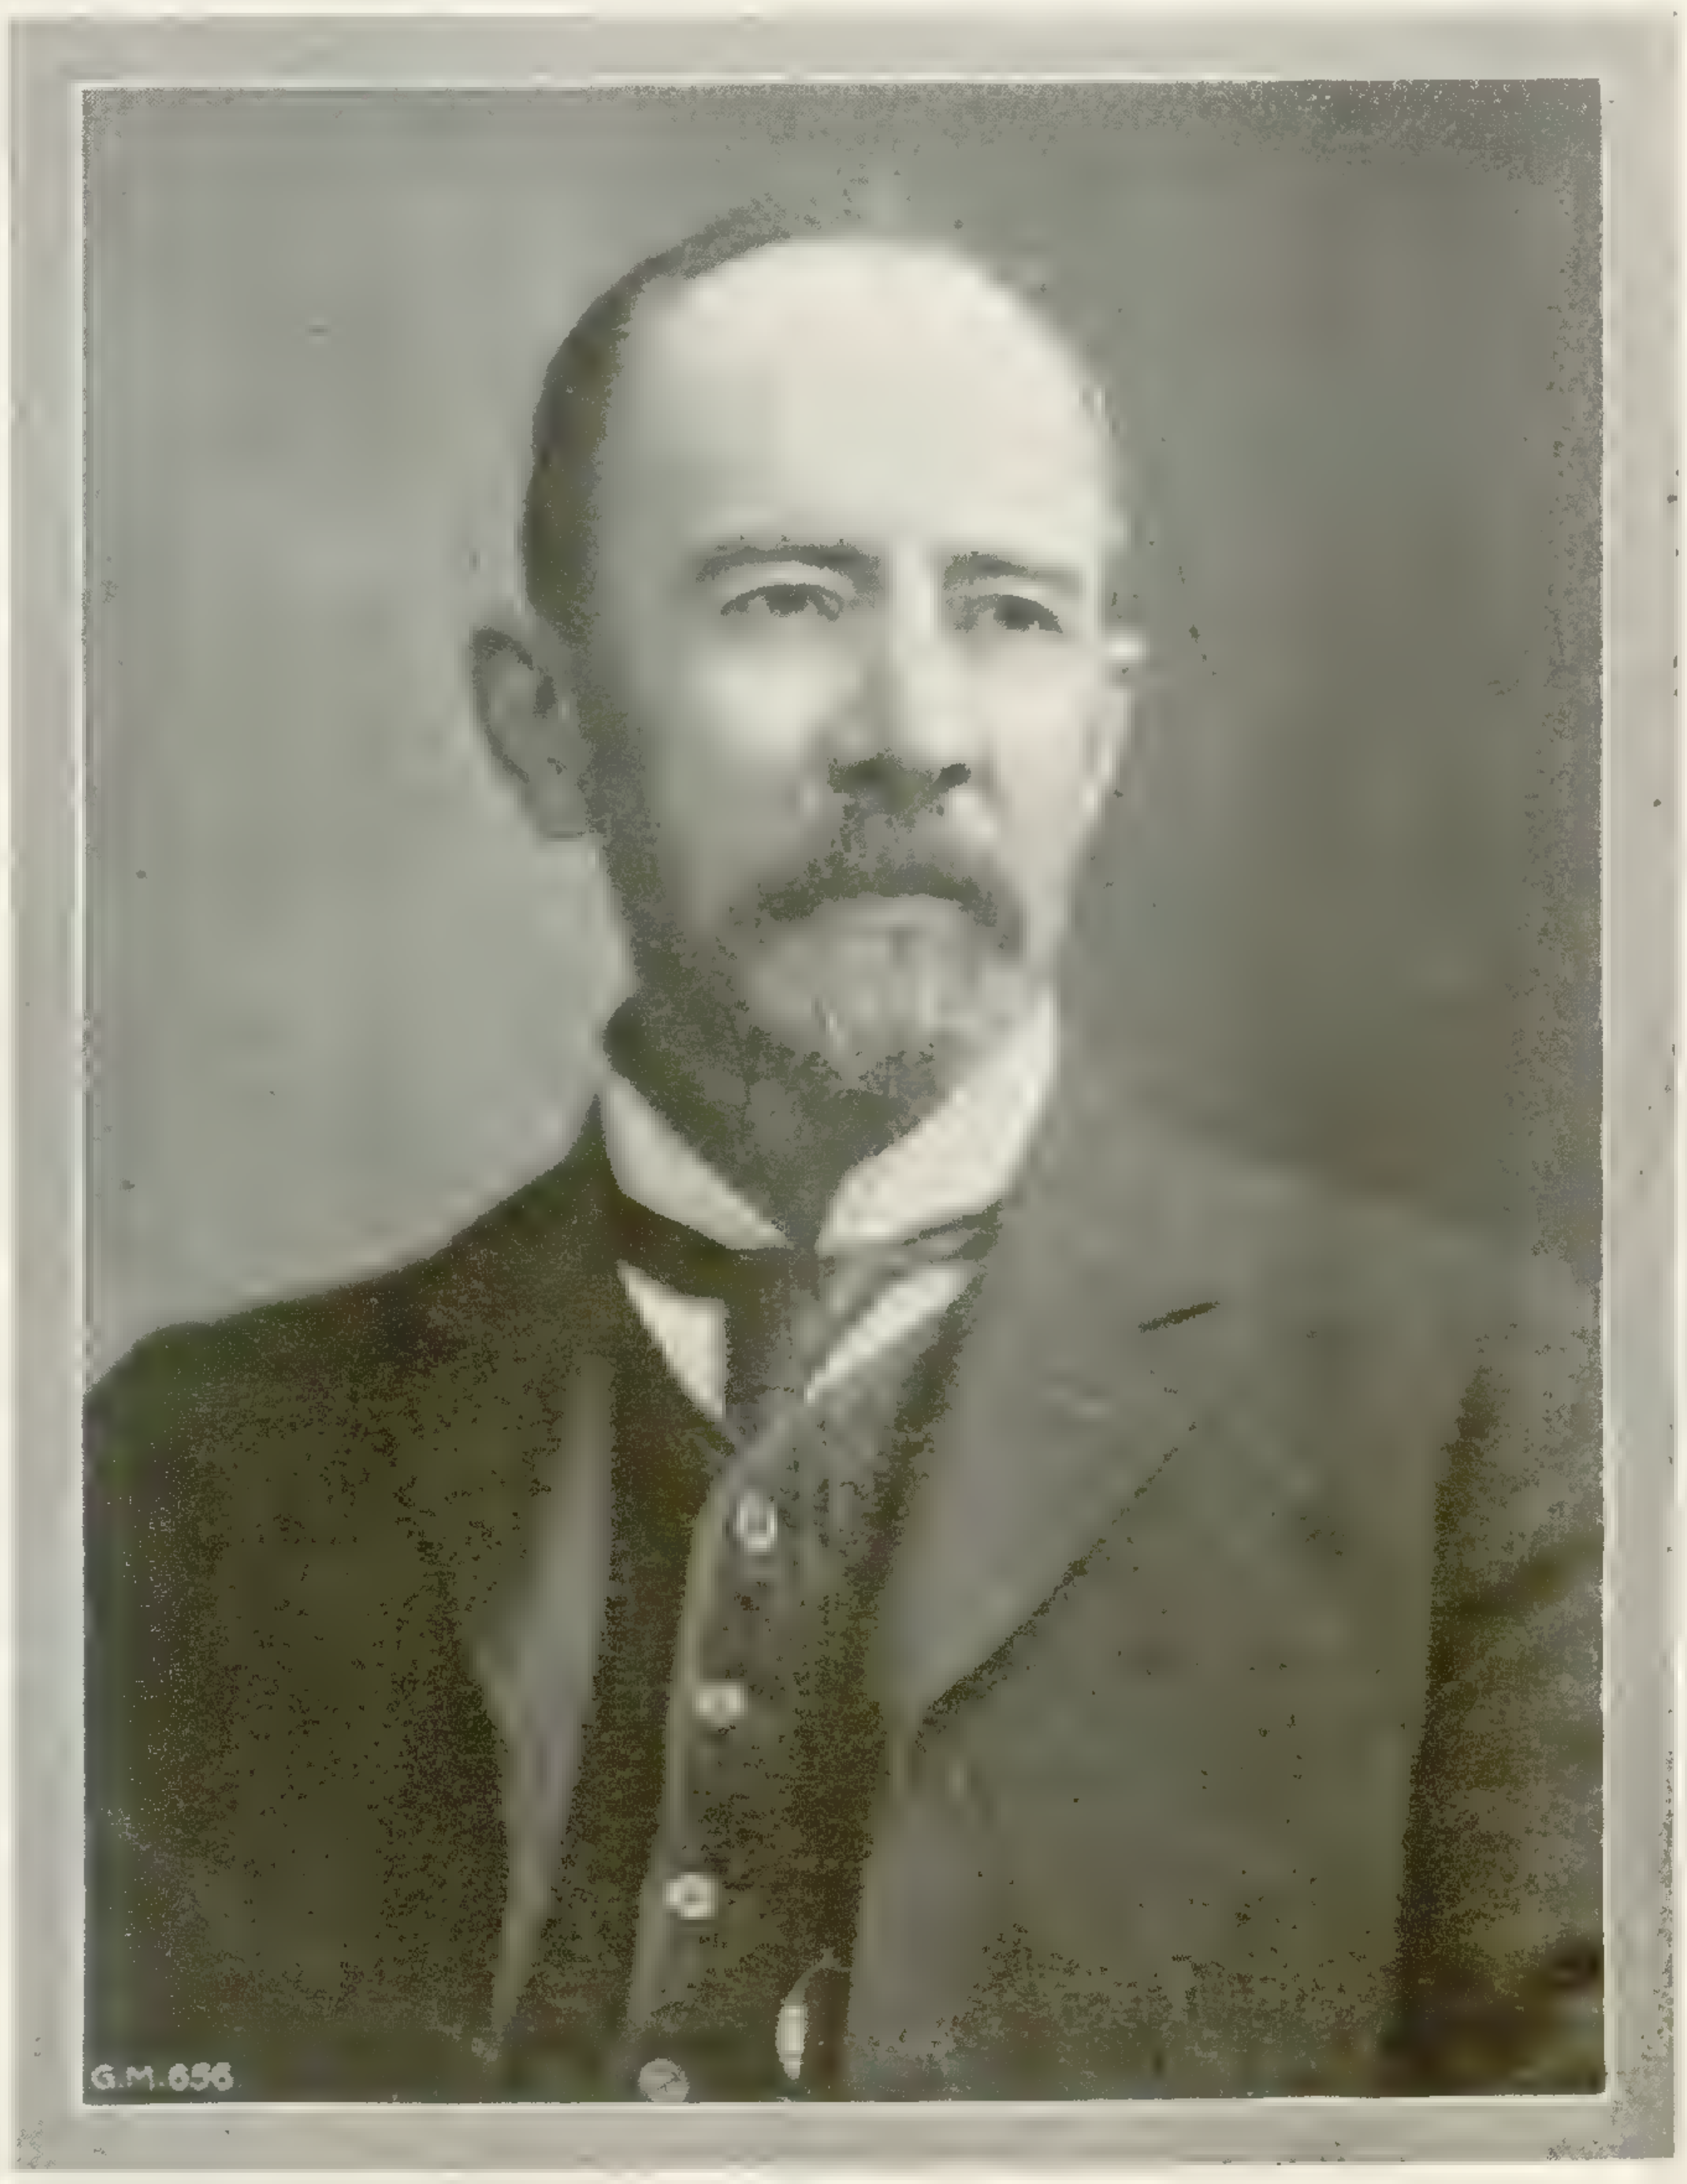
NOTES OF THE WEEK.

◆

Vegetable Structure.

Undoubtedly it is in the vegetable kingdom that we find the most remarkable instances of economy of structural material combined with great strength, owing to the combination of tough fortifying tracery with padding of a resistant nature. An air bladder constitutes the ideal of such construction, where a thin skin is inflated with a body of air until, despite the tenuity of both skin and contents, it has all the resistance of an elastic solid body. Nature, however, in the plant world, uses water as the main ingredient in her most economical creations. Who would imagine when suffering the pangs of indigestion owing to consumption of the succulent cucumber, that over 95 per cent. of that very solid-looking vegetable is water pure and simple, so that less than only one thin slice in a score would represent the really solid portion consumed. Marrows, gourds, melons, and most succulent fruits and vegetables are similarly constituted, the proportion of solid matter to liquid being relatively minute, despite the apparent solidity. If we examine such structures we shall find such solidity to be mainly due to the fact that they are built up entirely of minute cells distended by watery sap. Each cell has its tiny bladder-like skin, and is closely pressed against its neighbours, and it is the accumulated strength of myriads of these which, despite their individual fragility, imparts the strength and club-like hardness which the grown cucumber possesses. In some cases this internal mass of cells is permeated by a strengthening network of tougher make, as we may see in the familiar "Loofah" of our bathrooms, which is merely the skeleton of a species of gourd, and the lightness and tenacity of which gives us an additional example of strength and economy of material. In another direction, as exemplifying the same principle, if we study the grasses, or, indeed, any plants bearing hollow stems, we may see how beautifully a strong, supporting slender-walled tube, stiffened here and there with stouter rings (the knots or nodes), is contrived with a minimum of material, while in the Equisetums, or Horse-tails, we have these tubes beautifully grooved, meaning a further saving without depreciation of strength; and if we study the chemical construction we find a minute quantity of flint is distributed to harden and stiffen the whole to the utmost. It seems somewhat of a puzzle in this connection, and in others, how the delicate roots manage to dissolve the flint in the soil so as to distribute it in the foliage, since only the most powerful acids have any solvent effect on flint in the ordinary way, but plants have all sorts of round-about ways of getting what they need, by breaking up compounds already made and appropriating the needful. Structural economy we also see exemplified in the wonderful network of leaves. The leaf is designed to expose as large a number of cells as possible to the light and air, and the delicate tracery of the veins constitutes not merely a structural support, but also a marvellous system of sap supply akin to the water supply of a city. It is, however, far more wonderful than this, for the tiny pipes, main and minor, which traverse the veins, have a double duty to perform. Not merely do they convey water from the terrestrial root system which collects it, but they carry back into the general body of the tree the formative materials elaborated by the leaf cells under the stimulating influence of light, which contribute to build up the wood, the flowers, and the fruits, and also the underground root system. It is in this way that the largest tree has been built up. Season after season the foliage has not merely increased in extent, but in the process of extension it has strengthened trunk, branch, and twig with a fresh ring of wood to enable the general structure to withstand the increasing strain, and at the same time it has widened and strengthened the root system on precisely similar lines of adjustment. In the case of slender climbers, structural economy is effected by the gift of power to use the strength of neighbouring trees instead of their own, all sorts of clinging, clasping, and enveloping contrivances having been evolved to this end, to say nothing of actual parasitism like that of the Dodder, which is so selfishly economical that it bleeds its host to death to feed its own flowers and perfect its seed—a vegetable leech.



MR. W. HAYWARD MATHIAS.

Honorary Secretary of the Perpetual Flowering Carnation Society.

Mr. W. Hayward Mathias, whose portrait we present to our readers in the current issue, is a good example of an amateur rising to the front rank of professionalism as a result of keen love for flowers, and a careful study of their requirements. For a long number of years Mr. Mathias occupied a high position in the Civil Service, and in his leisure time he made carnations his special hobby in his pretty garden at Ditton, Surrey. He was one of the first to take up the culture of the winter-flowering or perpetual carnations, and eventually he created a large establishment for their culture at Medstead in Hampshire. Mr. Mathias has written a book, in conjunction with Mr. P. Smith, entitled "The Modern Carnation and How to Grow and Show It," and he has, from its institution, taken upon himself the lion's share of the work in connection with the "Perpetual Flowering Carnation Society," acting as hon. secretary and treasurer until the recent annual meeting, when the increasing work compelled him to resign the treasurership. Mr. Mathias is a hard worker, and at his home at Lucerne, Stubbington, Fareham, he keeps well abreast of the times with his favourite flower.

Charles Darwin Centenary.—In commemoration of the centenary of the birth of Charles Darwin and of the fiftieth anniversary of the publication of "The Origin of Species," the syndics of the Cambridge University Press will publish this spring a volume of essays entitled "Darwin and Modern Science." The essays will be preceded by an introductory letter from Sir Joseph Hooker, and by a biographical epitome, including the dates of Charles Darwin's books, and of the principal events in his life. The contributors include about thirty of the most distinguished botanists and biologists in this country and America and on the Continent of Europe.

Prizes for Allotments and Small Holdings.—The well-known weekly "Lloyd's News" has instituted a land culture competition in the interests of small holdings and allotments, in which £1,000 will be awarded in prizes. This competition will be open to all occupiers of small holdings and allotments in the counties of Berks, Buckingham, Cambridge, Essex, Norfolk, Oxford, and Suffolk, the awards will be made by judges appointed by Lord Carrington, President of the Board of Agriculture, and entries must be made not later than May 1. The competition is divided into three classes; in the first, prizes of £20, £10, and £5 will be awarded to the occupiers of the best cultivated small holdings of ten acres or more in each of the counties mentioned; in the second, class prizes of the same amount are offered for the best cultivated small holdings of less than ten acres in each of the counties, and the third is for allotments. In the class for allotments the prizes are of the same value as for small holdings, and will be awarded in each of the above counties for the best cultivated fields, or areas of not less than two acres, and cultivated by field labour, by eight or more members of the working classes. There are, in addition, two championship prizes of £50 in the two classes for small holdings.

United Horticultural Benefit and Provident Society.—The annual meeting of this society will be held at the Royal Horticultural Hall, Vincent Square, Westminster, on Monday, March 9, at 8 p.m. Mr. Charles H. Curtis will preside.

Dog Roses for Sale—a Warning.—Mr. Elisha J. Hicks, of Twyford, Berks, writes as follows: On Wednesday, February 24, three men were hawking plants at Twyford, and among other things they had "rose" trees. I had a look at the "roses," and, being a rosarian, was somewhat interested in the nice way in which they were named, tied up, and packed. Wondering what the varieties were I made a closer inspection and found labels inscribed with John Hopper, Crimson Rambler, Dorothy Perkins, Gloire de Dijon, Marechal Niel, and other well-known names. But as all the plants were alike in growth and wood, I looked still more closely, and found that, without a doubt, all the plants were Rosa arvensis, one of the many varieties of our dog rose! I give this as a warning to buyers, and express a hope that something may be done to stop such dishonest practices.

Upkeep of Epping Forest.—The cost of Epping Forest last year totalled £6,479. The chief items of expenditure were salaries, £890; keepers' wages, £1,195; labourers' wages, £1,050; rent, rates, taxes, and insurance, £390; repairs, £334; thinning trees, £776; golf course, £553; and making register of commoners, etc., £228. On the other side, the actual income is shown at £3,186, the principal items being: Boating rents, £500; sale of thinnings, £471; licences and tolls, £868; and golf course account, £809. The Court of Common Council voted £300 towards the cost of thinning the trees, and there remains a balance of £2,993 to be provided from City cash. It is estimated that there are upwards of 167 fallow deer in the forest.

Soil Inoculation.—Following the house dinner of the Horticultural Club, at the Hotel Windsor, S.W., at 6 p.m., on Tuesday, March 9, Professor Bottomley has promised to further discuss the question of "Soil Inoculation," in reply to Mr. Chittenden's criticisms in the Journal of the Royal Horticultural Society based on the Wisley experiments. Mr. Chittenden has also promised to attend and to take part in the discussion.

British Gardeners' Association.—The monthly meeting of the London Branch takes place on March 11 at 8 p.m., when Mr. A. E. Hameling of the firm of Messrs. Barrie and Brown, will give a lecture on "Insect Pests." All professional gardeners are invited to attend, and any wishing to join the B.G.A. can hand in their application forms during the business part of the meeting, which precedes the lecture.

Some Birmingham Gardens. In continuance of our series of articles on district gardens, we shall give, in our issues of March 13 and March 20, accounts of numerous leading and interesting gardens in and around Birmingham. The accounts will be freely illustrated, and they will describe such well-known establishments as Edgbaston Botanic Gardens, Canon Hill Park, Whetstone, Wyddrington, Southfield, Berrow Court, Harborne Hall, Perry Hall, and Queen's Park.

An Important Irish Law Case.—In May of last year Messrs. Alex. Dickson and Sons, Royal Irish Nurseries, Newtownards, co. Down, brought, in the Rolls Court, Dublin, an action by which they sought to obtain an injunction to restrain the defendants, Alexander Dickson, Joseph Dickson, and Alexander Dickson, junior, from selling any roses or seeds not grown or propagated by the plaintiffs, as "Dickson's roses" or "Dickson's seeds," or as "Dickson's pedigree seeds," or "Dickson's Irish seeds," and from carrying on the business of nurserymen or seedsmen under the name of Alexander Dickson and Sons or Alex. Dickson and Sons, while not in partnership with each other, and from carrying on such business under either of these titles or under any style in which the name "Dickson" appeared without taking reasonable precautions clearly to distinguish the business carried on. The injunction was granted by the Master of the Rolls on May 9, 1908, and against the order then made the defendant, Mr. Alexander Dickson, Woodlawn Nurseries, Dundrum, co. Dublin, and Parliament Street, and Essex Street, Dublin, appealed. The appeal was heard in the Court of Appeal, Dublin, before the Lord Chancellor, Lord Justice FitzGibbon, and Lord Justice Holmes. On Wednesday, February 25, judgment was given by the Lord Chancellor, dismissing the appeal, with costs; but the form of the injunction was varied, restraining the defendant from carrying on the business of nurseryman or seedsman either in the name of Alexander Dickson and Sons, or Alex. Dickson and Sons, or in any name or any manner to mislead the public.

Monthly Returns of Visitors to Kew in 1908.—The detailed monthly returns of the visitors to the Royal Gardens, Kew, in 1908, is as follows: January, 34,807; February, 55,896; March, 76,01[illegible]; April, 200,203; May, 482,732; June, 462,137; July, 340,286; August, 493,694; September, 237,515; October, 209,988; November, 88,947; December, 28,000; total, 2,710,220.
